For Aquinas as for Leibniz, without some positive predicates there would be no subject, and he rejects the more extreme negative way of Maimonides, for whom affirmative statements had only a negative content. Aquinas argues that this would not explain why we prefer some affirmative statements to others, would imply that God existed, was good, and so on, only in a secondary sense, and would be contrary to the intention of those speaking about God. Maimonides may have thought that our statements lock onto God as their object only because they are given direction by an adherence to God's law inspired from the heart. Aquinas would have replied that the love of heart or will, as distinct from sensory love, presupposes some knowledge by intellect, a reply also telling against more recent noncognitive approaches (see Mitchell 1971).

The completeness of Aquinas' embracing of the negative way appears in his exposition of God's simplicity (*Summa theologiae* Ia, q.3), where he successively announces different facets of the unlikeness between God and creatures immediately after proving God's existence (see Simplicity, divine §§1-2). This unlikeness is above all plain in God's different way of possessing existence; God alone possesses it intrinsically, is able to communicate it (*Summa theologiae* q.45, a.5; q.104, a.1), contains only active rather than passive potentiality, and is the ultimate cause of the being and continuance of anything with any real kind of contingency. Aquinas views God's act of existing (identical with his acts of living, knowing and loving) as identical with what he is (his *essentia*, his stuff, being or nature).

This last embodies Aquinas' rejection of self-causation, but its key importance is in marking the misleadingness of the ordinary structures of human language when applied to God. The subject/predicate structure of our statements does not make them false with regard to God, but makes them misleading. True, God exists, lives and loves, but our linguistic way of speaking ('by composition and division') suggests distinctions between the subject and the attribute predicated which are not real in the case of God. A term's 'way of signifying' (*modus significandi*) differs according to whether it signifies concretely ('God' or *Deus*, 'wise' or 'is wise') or abstractly ('deity', 'wisdom'), although the thing signified (*res significata*) is the same. Although we can make true statements about God, our language-formed way of thinking is in this way radically inappropriate, suggesting (for example) that God is one among many others who live, are good, know, act and exist. On the contrary, he cannot be grouped with them in the same genus - even the widest - as if the terms concerned might apply in the same sense or way. Rather, God not only exemplifies these attributes more perfectly, but also is his own life, goodness, and so on, and is the archetype (cause and *principium*) of life, goodness, and so on, in others - and this eminence implies the denial of every finite mode of possession of these attributes. Such is Aquinas' conception. At the same time, he always assumes the concreteness of God, the three divine persons being three primary substances in Aristotle's sense, rejecting the idea that God might be Existence, Life and Love in the Platonic sense of abstracted common properties shared by things which exist, live or love.

3 Later developments

The importance of the negative way appears in its contrast with rival, more positive theologies. Duns Scotus insisted that the terms for the divine perfections are used in the same sense of God and of creatures (univocally, not merely analogously), a view extended in Descartes' conception that we have a clear and distinct idea of infinity as attributed to God, as well as of these perfections. More recently, an empiricist natural theology has tended to model accounts of the relation between God and the world on a dualist conception of the relation between mind and body, and to rely on arguments for God from design (thinking of God's motivations in a parallel way to human ones) more than on cosmological arguments. This seemingly more common-sense approach rejects traditional ideas of God's simplicity, non-temporal nature and foreknowledge, and conceives his eternity only as an everlasting existence in parallel with creation, and therefore as compatible with a changing or developing God, as in process theology (see Process theism §§1-3). Such empiricism tends to conceive infinity in terms of magnitude, rather than in terms of the negation of all finite properties and finite modes of realization of 'perfections' (see Mitchell 1971, papers 1-3).

This 'common-sense' theology thinks of our capacity to speak of God as based on a supposed likeness of God to creatures, supposing the terms we use to apply literally only to creatures and to God in a derived or secondary sense. Yet this might seem absurd or even blasphemous in the case of the so-called 'perfections' - as if God could exist in a less real sense than his creatures, live, know, understand, love, be good or have active or causal power in a less full sense than creatures. In the older view the terms applied unrestrictedly to God, but only in some limited ('finite') respect to creatures.

These tendencies encourage an idolatry of creature-likeness in place of the Platonic idolatry that makes God an abstract entity; both these were rejected by Aquinas, and both invited Pascal's reaction, that the God of Abraham, Isaac and Jacob is not the god of the philosophers. Since 1700, the antipathy of theologians and spiritual men and women towards philosophical theology has steadily intensified. This reaction, rejecting Hegel's idea that God's nature and purposes can be read from history, reached its extremes in Kierkegaard and Karl Barth.

4 The negative way and arguments about meaningfulness

Does the negative way destroy the possibility of religious language's having any cognitive meaning? In the classic picture, since we know various positive statements about God to be true, and thence also know them to be meaningful (in the strong sense of being coherent enough to be capable of truth), some content remains, and not mere nonsense, even after all our negative qualifications. What we say, whether from revelation or tradition or from these assisted by philosophy, constitutes a pointer, and, in a structure of related statements, embodies some beginnings of thought or understanding, albeit not comprehension. It may contain paradox, defeating the imagination, but not intrinsic self-contradiction. Atheism and agnosticism, however, transform this situation: if we do not know that what is said is true, we have no way of knowing that any cognitive content at all remains behind after so many negative qualifications together with the adverbs 'infinitely' or 'unsurpassably'. The idea of the

infinite as a degree of intensive magnitude is unhelpful, since the atheist or agnostic has been given no reason why there should be any maximum in modes of existence, life, goodness, knowledge, love or causal power. There is then no ground for supposing these statements meaningful in any fuller sense than science-fiction stories or fairy tales - indeed they lack even the benefit of the imaginability that gives these stories their power.

This problem, of whether religious language has any cognitive meaning, is not just insoluble for the atheist and agnostic, but for any philosophy of religion which makes it a point of method always to consider questions about the meaning of types of statement (in this case, about God) in advance of considering their truth - as if to agree a neutral ground specific to the philosophy of religion from which to debate with agnostics or atheists. The supposed problem of meaningfulness is only solvable if knowledge of the truth of at least some of a class of statements is prior to knowledge of meaningfulness - for example, because given by revelation (the only solution admitted in Karl Barth's theology), by philosophy (questions of the meaningfulness of the terms we use being resolved in general philosophy, before we turn to using the same terms with regard to God) or somehow by 'experience'. Always some have assumed truth on the basis of faith, independently of and prior to considering how meaningfulness arises, and this has allowed a negative theology grounded in faith to be endemic, sometimes in distinguished figures scarcely noticed by later tradition, such as Nicholas of Cusa.

Older Jewish, Christian and Muslim traditions are strongly set against appeals to 'experience' as the key to knowledge of truth and meaningfulness. In this life, we know God by faith, not by sight; inner or outer experience can always be supposed in retrospect or by another person to have a different explanation from that which the experiencer thought certain at the time, and therefore cannot be the basis of the certainty of faith. If we follow the phenomenologists and Wittgenstein, no two 'religious experiences' described in quite different terms with different kinds of object or relations to different systems of motivation could be the same. The writings of R.C. Zaehner are typical of many suggesting just such differences (see Zaehner 1958). But with the increase of emphasis on 'experience' in religion over the nineteenth and twentieth centuries (see Phenomenology of religion §§1-2), and the decrease in the value put on teaching, ritual and reasoning in this sphere, the negative way has eased the way towards supposing that all the main world religions are set on the same objects and values, whether the 'ultimate' is described in impersonal or personal terms.

Nemesius (*fl. c.*390-400 AD)

Nemesius' treatise De natura hominis (On the Nature of Man) is the first work by a Christian thinker dedicated to articulating a comprehensive philosophical anthropology. Like many of his pagan and Christian contemporaries, Nemesius employs Platonic, Aristotelian and Stoic ethical psychologies in developing his views, but he also provides remarkably detailed accounts of the physiological structure and function of the sense-faculties based on extensive medical knowledge.

Information on the life of Nemesius is limited. He probably became bishop of Emesa in Syria during the last decade of the fourth century AD, and his philosophical treatise *De natura hominis (On the Nature of Man)*, written in Greek, dates from this same period. As late as the Middle Ages this work was attributed to Gregory of Nyssa, his better known contemporary, though seventh-century writers such as Maximus Confessor recognized Nemesius as the author. Such confusion was common in a literary tradition which stipulated an impersonal style of writing, often accompanied by an injunction to avoid originality.

Nemesius received an excellent liberal Greek education, which was broadened to include extensive knowledge of the medical tradition stemming from Hippocrates and Galen and deep familiarity with the spiritual metaphysics of late antique Neoplatonism (see Hippocratic medicine; Neoplatonism). Scientific knowledge about the human body and its physiological functions is harmonized with the Platonic doctrine of the soul; Aristotle's theory of free choice (see Aristotle) is reconciled with Christian providence. Nemesius relies heavily on the voluminous writings of Galen on anatomy and physiology. His treatise is a rich source of information on a wide variety of topics and on lost works by Galen and by other Christian authors, such as the *Commentary on Genesis* of Origen. The localizations of the sense and cognitive faculties in various parts of the brain were transmitted to Albert the Great and Thomas Aquinas in the thirteenth century by Latin translations of *De natura hominis*.

Despite the rich philosophical and scientific content of the work, its focus is religious and spiritual. It is clearly a piece of Christian apologetic addressed to Hellenic intellectuals not yet committed to Christianity. Nemesius' informative, multi-layered doxography, with its extensive medical knowledge of the body, made for an anthropology sophisticated enough for educated Hellenes yet also consonant with Christian doctrines. This interest in the concrete is reflected in his theological adherence to the school of Antioch, which stressed the historical character of the Gospel and the humanity of Christ.

The long and important first three chapters of the treatise aim at harmonizing Platonic and Aristotelian psychology and Platonic and Stoic metaphysics. On the latter topic, Nemesius endorses the Platonic/Neoplatonic hierarchy and continuity of being, but stresses the continuity from one level to the next, from inanimate entities through animals to human beings and beyond to the intelligible world. He objects to the radically transcendent character of Neoplatonism because it leaves discontinuous gaps in the structure of reality. This more vitalistic and less hierarchical metaphysic has been traced by some to the influence of the first-century BC Platonizing Stoic Posidonius of Apamea, parts of whose largely lost works may have been preserved in Origen's lost *Commentary on Genesis*. At the centre of the picture, Nemesius situates human nature as the link between the spiritual realm and the physical universe.

In the important second chapter on the soul, Nemesius begins with an extensive doxographical survey of psychological theories from the Presocratics through Aristotle, the Stoics, Epicureans, Neoplatonists, various Christian authors and the Manicheans (see Presocratic philosophy; Stoicism; Epicureanism; Manicheism). Adopting Plato's view that the soul is an independent substance, he rejects Aristotle's claim that the soul is a part of the composite human being. For Nemesius, then, the soul is a self-moving, incorporeal and immortal principle which employs the body as its instrument; it is not the body's perfection or entelechy, as Aristotle held. Chapter 3 of *De natura hominis* tackles a basic problem: if soul and body comprise some sort of unity, how can the soul be immortal? Nemesius relies on Neoplatonists who argued that in its essence the soul is an immutable substance which, when united with a body, suffers no change or alteration. He illustrates the relation between soul and body by comparison with Christological doctrine: the being of the Logos is not diminished when united with human nature (see Soul, nature and immortality of the).

Subsequent chapters take up the location of various faculties in bodily structures and their physiological description. Chapters 6-11 respectively cover imagination, sight, touch (which is defined as the ‘consciousness of feeling due to nerves proceeding from the brain and spreading into every part of the body’), taste, hearing and smell, which are located in the frontal lobes of the brain; intellect is located in the middle of the brain (Chapter 12), and memory in the back lobes (Chapter 13). A distinctive feature of the localization of the sense-faculties in parts of the brain is the citation of empirical evidence (for example, brain lesions) derived from Galen. Chapter 13 also reveals Nemesius’ commitment to the Neoplatonic doctrine of the pre-existence of the soul in which souls recollect things they learned in the intelligible world before taking birth in bodies.

Various models of parts of the soul are reviewed in chapter 15. His analysis of the passions and pleasures in Chapters 16-18 relies on Epicurus’ distinction among natural, necessary and non-necessary desires which is grafted on to the Platonic tripartite model of the soul, consisting of rational, emotional and appetitive parts. Discussion of the nutritive, generative and life-sustaining faculties or capacities in Chapters 23-8 closely follows Galen. Chapters 29-34 develop a largely Aristotelian theory of action which adroitly employs Aristotle’s accounts of the voluntary, involuntary, deliberation and choice. In the ensuing Chapters 35-40, Nemesius relies on the power of human deliberative rationality to ground his attack on fatalism and his argument in favour of the freedom of the will (see Free will). Some have seen in this account of freedom and rationality evidence of Pelagian optimism about human nature (see Pelagianism). Nemesius insists, however, that free choice is a divine gift and that it is exercised exclusively within the orbit of God’s providence (Chapters 42-4).

Neo-Confucian philosophy

Chinese neo-Confucian philosophy, or 'neo-Confucianism', is a term which refers to a wide variety of substantially different Chinese thinkers from the Song dynasty (960-1279) through the Qing dynasty (1644-1911). In at least one respect the term is misleading, for unlike Neoplatonists, most neo-Confucians saw themselves as reviving, not revising, the earlier Confucian tradition. What united all these thinkers was a common allegiance to Confucius and his thought. Many of the central debates within the tradition concern the issue of who could claim to be Confucius' legitimate heir.

Despite their shared dedication to Confucius' legacy, a number of the central beliefs of neo-Confucians were unknown to Confucius and his early followers and appear to be at odds with early Confucian views. Many of these beliefs were part of a novel, elaborate and comprehensive metaphysical scheme linking human beings (as microcosm) to the universe (as macrocosm). Such cosmological theories provided a new ground for Confucian ethical claims and strengthened a tendency towards the mystical identification of the self with the universe. These changes also helped to transform the earlier Confucian concern with self-cultivation and steady moral improvement to a more dramatic quest for spiritual enlightenment, replete with a distinctly Confucian style of meditation.

One widely accepted account of the rise of neo-Confucianism sees it as a reaction on the part of Confucian scholars to the perceived dominance of Buddhist thought. On this view, Confucians had become complacent in the period between the end of the Han dynasty, in the early third century AD, to the beginnings of the neo-Confucian movement late in the ninth century. Fearing that their way of life was in peril, these later Confucians resolved to overcome their Buddhist competitors and revive their tradition. Purportedly, these later Confucians realized that in order to accomplish these goals they would need to develop and deploy an account of the Confucian tradition that could compete with and overcome the complex metaphysical schemes the Buddhists had used to argue against them. For these strategic reasons, early neo-Confucians focused their attention on texts like the Mengzi (Mencius), Daxue (Great Learning) and Zhongyong (Doctrine of the Mean) and began to evolve a version of Confucianism that was supported by the kind of comprehensive and complex metaphysical system described above.

A different account of the rise of neo-Confucianism can be given, however, in which the selection of certain texts and the development of new styles and practices of reasoning are not seen as self-conscious strategic borrowings from Buddhism and Daoism. Rather, these characteristic features of neo-Confucianism are consequences of the profound and pervasive effect that Buddhist and Daoist thought had exerted for centuries upon Chinese intellectuals. There was no organized or distinct group of thinkers who identified and thought of themselves as Confucians in the centuries immediately prior to the neo-Confucian revival. Rather, Chinese intellectuals had come to accept a wide range of philosophical ideas and spiritual practices as part and parcel of literati culture. When certain of these broadly read and eclectically trained individuals began looking back to the writings of early Confucian figures, they did so through the categories and with the concerns and approaches of their age. Their angle of vision had changed, and as a result they saw these earlier sources differently. This new orientation led them to elevate certain texts to canonical status; in some cases, these were texts that were unknown to the sages they claimed to follow. Moreover, these later Confucians developed particular aspects of the classical writings in ways that would have been unrecognizable to the founding figures of the tradition they so adamantly defended.

The great impetus for the revival of Confucianism came with a series of social and political crises that came to a head roughly in the middle of the eighth century. Under the dual pressures of internal rebellion and economic distress and external attack on a number of different fronts, Chinese intellectuals began to question their fundamental beliefs and practices. Rather than calling for reform or progress, such reflection led them back to their roots. Increasingly, they came to believe that the primary source of their troubles was that they had lost their Way. Like the foreign enemies who plagued them from without, they were being undermined by a foreign force from within: the non-Chinese religion of Buddhism and its spiritual cousin Daoism. These had led them to abandon the true source of their strength and former glory: the culture of classical China. Their course was clear. They must retrieve and revive the classical culture that was their very essence. In so doing they would replay the roles their most revered sages, Confucius and Mencius, had played in their own degenerate ages. This call to defend and promote 'this culture' served as the rallying point for the neo-Confucian movement.

Towards the end of the neo-Confucian period, Chinese Confucians themselves began to recognize the degree to which earlier neo-Confucians had incorporated beliefs and styles of reasoning that were alien to Confucius' way of thinking, specifically ideas drawn from Buddhism and Daoism, into the tradition. A number of these Qing dynasty thinkers saw their task primarily in terms of purging the tradition of these foreign elements in an effort to reconstitute a purer form of Confucius' original vision.

1 Historical background

During the 'Northern and Southern Dynasties' (AD 317-588), China experienced a prolonged period of instability and upheaval. Buddhism, which had arrived in China as early as the first century AD, became the dominant religious and intellectual force in the country (see Buddhist philosophy, Chinese). Daoism also flourished and became a powerful and elaborate institutional religion (see Daoist philosophy). Under the short-lived Sui dynasty (589-618), Buddhism was adopted and promoted as the state ideology, and it continued to flourish and develop in the succeeding Tang dynasty (618-905). This period witnessed prolific growth in Buddhist philosophical ideas and systems of thought, several of which were to have a profound effect on neo-Confucian philosophy. Daoism also continued to exert a strong and pervasive influence throughout Chinese society. The Tang imperial family claimed one of the mythical founders of Daoism, Laozi, as an ancestor and actively supported and practiced Daoism.

These three traditions, Confucianism, Daoism and Buddhism, did not always coexist peacefully. There were a number of Buddhist persecutions instigated by Confucian and Daoist elements within the imperial court. The worst of these occurred during the Tang dynasty, from 841-5, when a Daoist emperor launched a severe and wide-ranging persecution of Buddhism. To a large extent, this reaction against Buddhism was brought on by the decline of Chinese political and economic fortunes in the closing years of the Tang. This anti-Buddhist sentiment was to play a major role in the resurgence of Confucianism.

The founding of the Sui dynasty had marked the revival of a centralized Chinese state. With it came bureaucratic institutions and practices, among them the civil service examinations, modelled on paradigms drawn from the earlier Han dynasty (206 BC-AD 220). The Sui rulers turned to these neglected Confucian institutions and practices as the most effective available means of organizing and governing their state. However, there was little concomitant interest in the philosophical ideas behind these institutions and practices. Buddhism and Daoism continued to be the primary interests of intellectuals during the Sui dynasty and throughout most of the Tang dynasty.

In the middle of the Tang period, the Chinese empire began to experience intense economic and political strain. Because of rapid population growth, increased fluidity between socio-economic classes, the monetary drain of large, tax-exempt monastic estates, rising military expenditures and a lack of leadership by the imperial court, the tax system began to break down. In addition to these economic woes, in 751 the Chinese state suffered defeat in two important military campaigns, against a Thai army in the south and an Arab army in the west. These military debacles precipitated a disastrous internal rebellion by a young general named An Lushan in 755. After this, the Tang court was never again fully in control of China.

Not long after these events, Han Yu began what was to become the Confucian revival. His blistering criticisms of Buddhism as a socially parasitic and quintessentially anti-Chinese religion are among the earliest and most powerful statements of sentiments that were coming to the surface during the later Tang dynasty, feelings fuelled by the indignation and frustration arising from the economic and political difficulties described above. Han Yu's condemnation of Buddhism as a foreign system of thought which had invaded China and weakened it - laying the ground for the foreign invaders who were now plaguing Chinese territory - provided a focus and point of departure for what was to come.

Han Yu argued that the Chinese needed to rid themselves of this foreign influence and return to their true roots. These ran back to Confucius and the idealized past culture which he preserved and advocated. Daoism and Buddhism were both accused of being 'other-worldly' and incapable of providing guidance in the all too real world of domestic and foreign challenges. Han Yu himself was not philosophically inclined. His great talent was literature, and his belief in the need to revive ancient literary style expresses both his own predilection and the degree to which he saw ideas in terms of the specific cultural practices of an idealized past. Nevertheless, he provided the founding vision and voice for the Confucian revival.

2 Central concepts and terms

Traditional accounts of the rise of neo-Confucianism agree in describing it as a reaction against Buddhism and Daoism. However, most overlook the economic and political events which precipitated this reaction. Moreover, they contend that the central texts and ideas which neo-Confucians embraced were consciously chosen for their efficacy in the fight against Buddhist and Daoist thought. According to such accounts, texts such as the *Mengzi (Mencius)*, *Daxue (Great Learning)* and *Zhongyong (Doctrine of the Mean)* were chosen because these were the best sources from which to draw in defending Confucianism (see Daxue; Mencius; Zhongyong). The present account differs from this view in seeing the choice of texts and ideas as a consequence of the pervasive and profound influence exerted by Buddhism and Daoism throughout the Chinese intellectual world of this period. When Confucians of the Song dynasty looked back to the early sources of their tradition, they saw them through many layers of Buddhist and Daoist influence. This altered their perception of what was most central to the tradition as well as their understanding of traditional philosophical concepts. In order to understand neo-Confucianism, it is important to realize how some of these ideas evolved.

Through its interaction with indigenous Chinese thought, particularly Daoism, Buddhism changed dramatically and developed distinctively Chinese forms. The early Buddhist belief that all imperfect aspects of reality are ultimately unreal became transformed into the idea that our less savoury aspects are not really part of our nature. According to this view, our fundamental nature is equally the nature of all things, part of a transpersonal *foxing* (Buddha-nature) which is reflected in each and every thing in the world. Once one realizes that one is part of all reality, one no longer will feel the inevitable anxiety and fear of the eventual loss of one's self at death; instead one comes to see the common belief in an enduring and separate self as the source of all suffering. A person with this 'right' view of things manifests universal compassion towards all sentient beings, as manifestations of Buddha-nature (see Buddhist philosophy, Chinese).

Since the beginning of their tradition, Confucians had offered competing theories about the true character of human nature (see Xing). It was therefore natural that the notion of Buddha-nature had a profound influence on neo-Confucian views. Neo-Confucians began to talk about *benxing* (original nature) and *qizhi zhixing* (material nature), the former perfect and complete, the latter flawed and needing refinement. These terms are not found in pre-Buddhist Chinese philosophy. Within this conceptual scheme, Mencius' claim about the original goodness of human nature came to be understood as referring to the original, perfect and pure state of human nature rather than to certain of its nascent tendencies (see Mencius).

In order to appreciate fully this new view of human nature, we need to understand two additional neo-Confucian terms of art: *li* and *qi*. *Li* ('pattern' or 'principle') appears in early Daoist texts and means the underlying pattern running throughout the world. Different things, including human beings, possess their own individual structures or 'patterns' and contribute to a larger, grand 'pattern' or scheme (see Li). Under the influence of Buddhist philosophy, particularly the notion of Buddha nature as described above, this concept changed dramatically. The underlying pattern of the universe came to be seen as completely present in every mote of dust, with each aspect of reality reflecting all others.

However, neo-Confucians believed that any given thing only manifests certain particular *li* and this is what makes a thing the thing it is. Only certain *li* are manifested because of the effect of *qi* (ether). *Qi* is what makes up the world. It is a kind of lively - not inert - matter which exists in various grades of purity. As a function of its purity, the *qi* of different things obscures, to varying degrees, the *li* that are within them, only allowing some to shine through. So while all things equally possess all the *li*, their different endowments of *qi* make them different. Human beings are unique in that they alone have the ability to become aware of the *li* within them by refining their *qi* to the highly tenuous state which allows all the *li* within to shine forth. Other creatures are stuck at different levels of 'clarity'; the *qi* of inanimate things is so 'dense' that they lack consciousness (see Qi). Neo-Confucians tended to equate *li* with the 'original nature' of human beings and contrasted this with the idea of 'material nature', which is *li* embedded in *qi*. The task of moral self-cultivation was to refine one's *qi* and move from relative ignorance to complete and comprehensive knowledge (see Self-cultivation in Chinese philosophy).

3 The Song dynasty (960-1279)

These terms of art and the basic concepts were developed and made systematic during the Song. In particular, the

speculative metaphysics that came to serve as the foundation for neo-Confucian philosophy was forged during the early part of the dynasty. These early Song thinkers did not always share the social, political and ethical concerns of later neo-Confucians.

Shao Yong was one of the first early Song figures associated with the rise of neo-Confucianism in the eleventh century. His major interest was explaining the cosmology of the *Yijing (Book of Changes)* (see Yijing). Shao is distinctive for linking his cosmological speculations to an elaborate system of numerology. In this regard, his thought is not unlike that of the Pythagoreans (see Pythagoreanism) or Leibniz, who was familiar with some of his ideas.

Shao assumed that there was a discernable correlation between the hexagrams of the *Yijing* and the structure and function of the universe. Hence, anyone with a proper understanding of the text could not only understand but foretell events in the world. He wove his philosophical system around a passage from the *Xicizhuan (Commentary on the Appended Phrases, also known as the Dazhuan (Great Commentary))* of the *Yijing*, which he believed described this relationship: ‘And so within the Changes is the *taiji* [Supreme Ultimate]. It produces the two Principles [symbolized by *yin* and *yang*]. The two Principles produce the four Forms. The four Forms produce the eight Trigrams’ (*Xicizhuan* A11). Shao read this passage in terms of numerology, relying upon the notion of *shen* (spirituality). *Shen* is an active and impersonal conscious power which both animates things in the world and allows one to understand them. It is able to act immediately at a distance, and as understanding can instantly ‘penetrate’ throughout the universe. Shao believed that *shen* produces numbers, corresponding to the initial distinction of *yin* and *yang* (see Yin-Yang), and that from number the ‘images’ of things (the four Forms) arise. These then generate the actual things and events in the world. Human beings have *shen* as part of their nature; they can therefore tap into its activity and understand its movement by grasping the underlying numbers which give rise to all things.

Following this scheme, Shao saw the world in terms of sets of four (corresponding to the four Forms): there were four earthly substances (water, fire, earth, stone), four livings things (animals, birds, grasses and trees) and so on. In addition to these fundamental classes of things, Shao used this scheme to describe four phases of history, which recur in unending cycles of fixed numerical length. He showed little interest in many of the basic issues that later came to characterize neo-Confucianism, and was not regarded by Zhu Xi (see §6) as part of the orthodox Confucian revival. Shao was neither anti-Buddhist nor anti-Daoist; he was not a moralist, a political or social reformer or a self-cultivationist. His most important work, the *Huangji jingshi (Supreme Principles Governing the World),* concerns as its title suggests the underlying patterns and principles of the universe. It is primarily a work of cosmology.

4 The Song dynasty (960-1279) (cont.)

Zhou Dunyi shared Shao Yong’s interest in the cosmology of the *Yijing*. However, he did not share Shao’s numerological theories, and his cosmological system placed human beings more clearly at the centre of the universe. He served briefly (1046-7) as a teacher of Cheng Hao and Cheng Yi (see §5). His two most important works, the *Taiji tushuo (Diagram Explaining the Supreme Ultimate)* and the *Tongshu (Comprehending the Book of Changes)* were instrumental in the development of neo-Confucian metaphysics. Zhu Xi regarded him as the founding figure of the neo-Confucian revival.

In the *Taiji tushuo*, Zhou presents a chart with accompanying commentary explaining how the Supreme Ultimate (*taiji*) contains within itself the two modes of stillness and activity. These give rise to *yin* and *yang* respectively. These produce the *wuxing* (five elements), which in turn generate the two fundamental principles: the heavenly principle, *qian*, and the earthly principle, *kun*. These then produce all the things in the world. Human beings are unique among creatures in that they receive the most pure forms of the five elements and thus are able to play a critical role in both understanding and guiding the course of the universe.

An important feature of Zhou Dunyi’s thought concerns the relationship between the unity of the *taiji* and the variety of things in the world. According to Zhou, the *taiji* produces the two fundamental *qi* ‘ethers’, *yin* and *yang*. As things take shape, they move through a progression of increasing distinctiveness; and yet, while they become separate individual things, all partake of the original unity of *taiji*. Zhou makes this idea explicit in his *Tongshu*, where he talks about how the myriad things are really one and the one is present in each of the myriad things. We

can see the ethical implications of this idea in a well-known anecdote about Zhou. He refused to cut the grass in front of his window, saying that he thought of the grass as he thought of himself. The idea that the universe is coextensive with oneself and that its comprehensive unity (*taiji*) is present in each and every aspect of it, becomes a cornerstone of neo-Confucian thought.

A source of considerable controversy among the neo-Confucians who followed Zhou was his equation of the Supreme Ultimate with *wuji*, the 'infinite' or 'ultimate of non-being'. Both these readings of *wuji* present problems. The first seems to be a tautology; the second seems perilously close to the Daoist claim that existence comes from non-existence, a claim most neo-Confucians would emphatically deny. However, *wuji* can be understood as describing the tenuous state of the universe prior to there being any discrete things present. Zhou would then be saying that this original undifferentiated state is the origin of all things.

Another point of controversy concerns Zhou's claim that one should make *jing* (stillness) one's guiding principle. The idea is that one should cultivate one's mind in order to attain the lucid and tenuous state of the *taiji* itself. The mind then can sympathetically detect the subtle, emerging form and direction of things, and one can act to maintain a state of universal harmony and balance. Cheng Yi, and later Zhu Xi, took exception to this aspect of Zhou's thought and sought to replace his emphasis on 'stillness' with an emphasis on another notion, represented by a different word (also pronounced *jing*) meaning 'reverential attention' (see §§5, 6).

Traditionally, Zhang Zai is the second great figure of neo-Confucianism. He was the uncle and teacher of Cheng Hao and Cheng Yi. His most important works include the *Zhengmeng (Correcting Delusions)* and the *Ximing (Western Inscription)*. The latter was originally part of the former work, but was inscribed on the west wall of Zhang's study and came to be regarded as a free standing text.

Zhang's thought was based on his interpretation of the *Yijing* and the *Zhongyong*. While he owed much to Zhou Dunyi and Shao Yong, he did not employ the charts that were central to their method of explication, nor did he show any interest in numerology. Zhang's interest in metaphysics was primarily as a guide to morals. He simplified earlier metaphysical theories, arguing that the *taiji* was simply undifferentiated *qi* (ether) which arises from an inchoate, primordial state called *taixu* (the supremely tenuous). The nature of human beings and all things contains all that is in the *taiji* and the human mind can attain knowledge of these things; the self and the universe are fundamentally one. However, in order for people to realize this unity they must attain a state of lucidity, purity and tenuousness, like that of the *taixu* itself, through a process of self-cultivation.

The driving thrust of Zhang's philosophy is this imperative to realize the fundamental unity of human beings with the rest of the universe. Zhang Zai described this goal as the task of forming one body with all things. Perhaps it would be more accurate to say the goal is realizing (both in the sense of grasping it intellectually and manifesting it personally) the underlying unity between the self and the universe. This idea is expressed beautifully in the opening section of his famous *Ximing*:

> Heaven is my father, earth my mother; even an insignificant creature such as I finds an intimate place between them. And so, all that fills the universe I take as my body and what gives it direction I take as my nature. All people are my brothers and sisters, all creatures my companions.

(*Ximing*)

5 The Song dynasty (960-1279) (cont.)

Cheng Hao and Cheng Yi were brothers responsible for the mature statement of neo-Confucianism. They elevated the notion of *li* ('pattern' or 'principle') to a pre-eminent position and identified the 'pattern' within things and events with *tianli* (heavenly principle), the pattern of the entire universe. Here we see an explicit statement of the idea (discussed in §2 above) of the universe being present in each of its parts. Cheng Yi is credited with the famous dictum: '*Li* is one but its manifestations are many.' The Chengs also explicitly equate this universal pattern or principle with *xing* (nature) and *xin* (mind) (see Xing; Xin (heart-and-mind)).

The Chengs do not talk about the notion of *taiji* and show little concern with how the universe evolved. Their metaphysical scheme consists of two fundamental notions: *li* (pattern) and *qi* (ether) (see Li; Qi). They are dualists but of a special kind. While they believe the universe is composed of these two constituents, they insist that *li* cannot be found apart from *qi*, and *qi* without *li* would lack any shape or meaning. In a sense, the distinction

between them is logical and not actual. For both brothers, the mind is *li*, and we come to understand the things of the world when we match up the *li* in our minds with the *li* of individual things and events (thus explaining the notorious problem of how we can recognize something as right). Most people are born with impure endowments of *qi* which prevents the *li* of their minds from properly matching up with things. Moral self-cultivation is the process of refining one's *qi* to remove the impediments to the *li* within. The ultimate result is complete and perfect knowledge of both self and the world.

The brothers differ most in their views concerning how to carry out this process of self-cultivation. Cheng Hao was the more mystical of the two and emphasized the power of moral intuition (in the sense of a feeling rather than an insight). He believed in a universal, creative spirit of life, *ren* (benevolence), which permeates all things just as *qi* permeates one's body. Playing on the multiple senses of the word *ren*, he likened an 'unfeeling' (that is, non-benevolent) person to one with an 'unfeeling' (paralyzed) limb. Neither realizes the unifying 'oneness' of themselves (in the case of the former, this involves failing to feel that he is 'one body' with all things). For Cheng Hao, the task is to locate and pay attention to this inner feeling and allow it to guide one throughout one's life.

Cheng Yi presented a more developed and detailed philosophical system. His method of self-cultivation urges one to awaken the *li* within the mind by perceiving the *li* within the world. One could do this by carefully attending to one's daily affairs, but since the classic texts of Confucianism present these 'patterns' in their clearest and most accessible form, the primary source for such understanding was study of the classics. In either case, as one came to understand a given *li* one was to *tui* ('extend' or 'infer') its interconnection with other *li* until one achieved a complete and comprehensive understanding of them all. This process must be carried out with an attitude of *jing* (reverential attention) in order to insure that one's knowledge is affectively appropriate as well as cognitively accurate. Such knowledge is *zhenzhi* (real knowledge) as opposed to *changzhi* (ordinary knowledge) (see Knowledge, concept of). Cheng Yi illustrates this distinction with an allegory about people who 'know' (that is, they have heard) that tigers are dangerous versus one who 'knows' because he has been mauled.

Both brothers employ a scheme of learning sketched in another text that was to become central to neo-Confucianism, the *Daxue (Great Learning)*. One was to *zhizhi* (extend knowledge) by *gewu* (investigating things). For Cheng Hao, this involved a regimen of introspection and internal self scrutiny with the aim of correcting any errant thoughts. For Cheng Yi, the process was more externally directed: one came to understand the world by a careful inspection of paradigmatic cases in the classics and practical problem solving in one's own life (see Moral education; Moral development; Self-cultivation in Chinese philosophy).

6 The Song dynasty (960-1279) (cont.)

Zhu Xi is rightfully regarded as the greatest neo-Confucian synthesizer. While he drew a great deal of his thought from Cheng Yi (see §5), he gave it novel form and introduced significant innovations of his own design. The system of thought that emerged quickly became one of the two primary 'schools' of neo-Confucianism: Cheng-Zhu Learning or *lixue*, the 'Learning of Principle'.

Zhu reintroduced Zhou Dunyi's term *taiji* (see §4) and explained that it is the sum of all the *li* in the universe. It exists before the universe comes into being and is reflected in every aspect of reality. He illustrated this latter point with the metaphor of the moon being reflected in countless bodies of water. Zhu was a stronger dualist than Cheng Yi, insisting that *li* existed before the universe did and would remain even if it were destroyed. However, at times he presents this as merely a notional, not real, possibility. For all practical purposes, one can never find *li* and *qi* apart from one another. This question generated a long and acrimonious debate among later neo-Confucians in China and Korea.

Zhu also emphasized a distinction between *daoxin* (the mind of the Way) and *renxin* (the human mind). The former was pure *li* and hence perfect; the latter was *li* embedded in *qi* and hence necessarily obscured and prone to error. The concept of *daoxin* was in a certain sense a limiting notion. Zhu did believe that people could attain this level of refinement (and become a sage), but even the minds of sages are a mixture of *li* and *qi* (albeit an extremely refined and limpid *qi*), and so they are still susceptible to error should they grow complacent. Given this view, even the sage must engage in a life of constant moral scrutiny.

Among Zhu Xi's many innovations was his grouping together of four texts, the *Analects*, *Mencius*, *Zhongyong* and *Daxue*, as a set called the 'Four Books'. This set soon became the core of neo-Confucian learning. Zhu's text and

commentaries to the Four Books served as the basis for public education and the civil service examinations from 1313 until 1905. Zhu also helped to shape the Chinese education system by working to establish *shuyuan* (academies), Confucian institutions modelled on Buddhist monastic schools. These served a critical role in the neo-Confucian tradition until they were absorbed into a system of state schools during the Qing dynasty.

Zhu Xi also established the notion of *daotong*, the 'transmission of the Way', as a central neo-Confucian concern. It was he who argued that the orthodox understanding of Confucius' teaching had been lost after Mencius and only recently retrieved by Zhou Dunyi, then handed down through Zhang Zai, the Cheng brothers and (by implication) to Zhu himself. Zhu's influence on later Confucian thinking and Chinese society cannot be overstated. His view of the later tradition and its place in the larger context of Chinese history still greatly influences contemporary scholarship on Chinese philosophy throughout the world.

Lu Xiangshan represented what became the main alternative 'school' within neo-Confucianism known as *xinxue*, the 'learning of the mind'. It was later associated with the thought of Wang Yangming (see §9) and so also came to be called 'Lu-Wang Learning'. Lu's metaphysical disagreements with Zhu Xi are slight but significant. They mainly concern the issue of the nature of the mind: Zhu held that the mind was *li* embedded in *qi*, whereas Lu insisted that the mind is *li*. In a related disagreement, Lu rejected Zhu's distinction between the 'mind of the Way' and the 'human mind', arguing that there is only one mind and that it is principle. These doctrinal differences reflect deep and important disagreements about the character of human nature and the proper method of moral self-cultivation. Lu believed that our true mind is an innate moral mind which we can access and bring to bear in all our thoughts and action. The deluded mind exists only because of a kind of self-deception regarding our true nature.

Lu saw Zhu Xi's strong dichotomy between *li* and *qi* as establishing a corresponding dichotomy between moral knowledge and human desire. Lu thought that if one embraced this dichotomy, one would come to see self-cultivation in terms of the suppression of one's emotions and the accumulation of disconnected empirical facts about the world instead of the discovery and cultivation of one's innate moral feelings. One would then come to confuse broad learning with moral wisdom. The effort to acquire such learning would lead one into competition with others, which would only further obscure one's innate moral feeling of benevolence for all. The knowledge being talked about here was primarily knowledge of classical texts, the kind of knowledge that was the primary prerequisite for success in the civil service exams; and so, another danger associated with Zhu's method was the confusion of the quest for moral wisdom with the search for worldly success.

In contrast to Zhu, Lu argued that the human mind (in particular, our moral sense) was both necessary and sufficient for self-cultivation. Without it, one would fail to develop the affective dimension of 'real knowledge'. If one could only keep one's innate moral sense before one, it would guide one to identify and remove and selfish desires obscuring the *li* of the mind. Lu's difference with Zhu can be seen in his attitude towards the classics. Lu was not opposed to study of the classics *per se*, but he thought that a deep and personal understanding of some small part of them was preferable to the comprehensive knowledge Zhu Xi recommended. In particular, Lu advocated coming to a personal understanding, a kind of *verstehen*, of the mind of the sages as revealed in the classics. His position follows easily from his belief in a transpersonal 'mind' shared by all people and is neatly summed up in his well-known maxim regarding study of the classics: 'If only one understands what is fundamental, the six classics are all one's footnotes' (see Chinese Classics; Xin (heart-and-mind); Self-cultivation in Chinese philosophy).

The differences between Lu and Zhu were made clear in two debates between them, held at Goose Lake Monastery in 1175. In these debates, the intimate relationship between their metaphysical differences and their views on moral self-cultivation are evident. Lu accused Zhu Xi of ignoring the task of *zundexing* (honoring the virtuous nature) at the expense of *dao wenxue* (pursuing inquiry and study). In effect, he was accusing Zhu of forsaking what was commonly regarded as the most fundamental tenant of Confucianism: the innate goodness of human nature. In reply, Zhu accused Lu of mistaking his own subjective view of things as universal truth. In essence, this was to accuse Lu of the ultimate neo-Confucian error: selfishness.

7 The Yuan dynasty (1280-1368)

The Yuan dynasty marked the beginning of nearly one hundred years of Mongol rule over China. During this

period, elite Chinese culture gave way to the nomadic, tribal customs of the conquering Mongols. In addition, the Chinese were exposed to a variety of other, equally alien cultural influences that came in the wake of far-ranging Mongol conquests. At the same time, Chinese influences were carried along in the flow of Mongol victories and spread to other lands.

While Mongol influence was strong at the court and higher echelons of Chinese society, it often coexisted peacefully with indigenous Chinese beliefs and practices and probably had little influence on the lives of the vast majority of Chinese. On the one hand, this was the result of the Mongol practice of general non-intervention in local customs and practices, due in part to their inability to manage their immense realm on a local level and in part to their tendency to tolerate diversity as long as it posed no threat. On the other hand, this policy was simply a function of the substantial numerical superiority of the Chinese. Like earlier conquerors of China, the Mongols realized that existing Confucian institutions were indispensable for ruling their newly-gained empire. These institutions helped preserve much of neo-Confucian thought and even contributed to its acceptance as the orthodox state ideology and its spread to foreign lands.

Cheng-Zhu Learning did particularly well during this period and in 1313 was officially adopted as the state orthodoxy. The reason for the triumph of this ‘school’ of neo-Confucianism and the decline of the teachings of Lu Xiangshan had a good deal to do with the relative superiority of Zhu Xi’s system as a basis for the civil service examinations. It was much more detailed, systematic and accessible. Zhu had composed extensive, meticulous and persuasive commentaries on all of the Chinese classics. He had provided a handy summary of Confucian learning in the form of the text of and accompanying commentaries on the Four Books, and he had also produced numerous anthologies and primers of Confucian learning. One of these, the *Xiaoxue (Elementary Learning)*, intended for the moral education of the young, found wide appeal among the Mongols themselves.

Zhu Xi’s thought provided a well-defined system that was basically quite conservative in nature, well-suited to the role of a bureaucratic ideology under occupation. This is not intended to slight the genuinely moral aspects of almost all of Zhu Xi’s writings; had his philosophy not provided concerned Chinese intellectuals with a powerful moral calling, it would undoubtedly not have succeeded as well as it did throughout the Yuan dynasty and on into our own time. Its great power lay precisely in its ability to channel moral and patriotic feelings in constructive directions under a variety of circumstances. Given the situation at the time, Zhu’s philosophy provided a way for the Chinese to continue their own culture and to a significant degree Sinicize the conquering Mongols. However, Zhu Xi’s philosophy is not easy to see as a revolutionary creed, and during the Yuan dynasty we see little if any of the philosophical creativity and debate that marked the preceding dynasty and the one to follow.

8 The Ming dynasty (1368-1644)

The Ming period marked a revival and development of Lu Xiangshan’s challenge to the Cheng-Zhu orthodoxy. One of the earliest figures in this movement was Chen Xianzhang, also known as Chen Baisha (1428-1500). Chen argued that the strong dualism of the Cheng-Zhu school did not reflect the central neo-Confucian belief in the inherent unity between human beings and the universe. In particular, the strong distinction between *li* and *qi* tended to value speculative theory and the intellect at the expense of practical concerns and the emotions. This resulted in a general distrust of feeling and intuition and a gross overemphasis on the intellect and study of the classics as the proper methods of moral self-cultivation.

Chen argued for the inherent unity of human beings and the universe. He also promoted the idea that human beings spontaneously move in harmony with the natural realm and fail to do so only when they impose their own selfish ideas upon the world. In this latter view in particular, as well as in several other aspects of Chen’s thought, one can see the influence of the early Daoist philosopher Zhuangzi.

Chen’s criticism of the Cheng-Zhu school’s overreliance on intellect and study and his belief in the reliability of spontaneous intuitions to guide human action shifted the focus of moral self-cultivation away from study of the classics and speculative philosophy and towardss reflection and self-scrutiny. One could describe this as a shift towards ‘subjectivity’, but only with the qualification that he believed the intuitions of properly cultivated individuals would agree in every significant respect. He was not advocating individual expression in the modern Western sense of expressing one’s unique individuality; he was encouraging the discovery and personal expression of a shared, transpersonal mind. Any strong sense that one’s actions were uniquely one’s own was a sign of

selfishness - not of the moral mind. Chen's views greatly diminished the prestige of the classics as the ultimate source of moral knowledge. In his view, individuals possessed a moral sense that was at least equal in value as a moral guide.

A related feature of Chen's views is his belief that moral judgments are highly context-sensitive. The difficult situations one encounters in life are so complex, nuanced and specific that no appeal to rules or precedents could ever provide adequate guidance. Fortunately, each person possesses an inherent moral guide which one can make contact with and engage through a process of reflection and inner self-scrutiny. This aspect of Chen's thought further eroded the status of the classics and with it the plausibility of the Cheng-Zhu school's entire approach to moral self-cultivation.

9 The Ming dynasty (1368-1644) (cont.)

Many of these ideas were taken up and developed into a powerful challenge to the Cheng-Zhu school by the most important Ming thinker, Wang Yangming. Like Chen, Wang emphasized that the goal of moral self-cultivation was to realize that one was 'one body' with all things. Also like Chen, he believed in an innate faculty of moral intuition and the critical need to rely upon this faculty in making moral judgments. And like both Lu Xiangshan and Chen, Wang believed that the mind itself is *li* (principle) (see Li). However, Wang developed these ideas in novel ways and combined them with others of his own design to produce a much more sophisticated and powerful philosophical system than either of these earlier thinkers.

Wang borrowed a term of art from Mencius in order to describe our innate and infallible moral sense: *liangzhi* (pure knowing). *Liangzhi* is an ever-present faculty that will spontaneously guide us in making proper moral judgments if only we can succeed in eliminating the selfish desires which normally obstruct it. We eliminate these by bringing them to complete awareness, where they are consumed by the light of *liangzhi*. The task is to maintain a constant state of internal scrutiny, monitoring our nascent thoughts to ferret out and eliminate any existing or emerging selfish thoughts.

Given this picture, Wang took issue with Zhu Xi's teachings on moral self-cultivation (see §6). Zhu believed that the major focus of one's effort should lie in coming to understand *li* by engaging in *gewu*, the 'investigation of things' (in other words, investigating the principles in the classics and in the world). Wang first objected to Zhu Xi's emendation and rearrangement of the text of the *Daxue* in support of this view, and advocated the original form of this classic. According to Wang, the original text shows that *gewu* is not a preliminary step in a process of acquiring knowledge of *li*; rather, it refers to the act of preserving the inherent integrity of the mind by 'correcting one's thoughts'. The task of moral self-cultivation thus does not rely upon the acquisition of knowledge through empirical inquiry, but rather the restoration and preservation of the mind through the elimination of incorrect (that is, selfish) thoughts (see Self-cultivation in Chinese philosophy).

According to Zhu Xi's interpretation of the text, one is to first cultivate one's virtue in order to care for all people. Wang insisted that these are simply different aspects of the same event. One cannot cultivate oneself *without* caring for others, and properly caring for others *is* cultivating oneself. Zhu Xi's view created a false division between the moral mind and the universe; Wang insisted that they were one. Zhu Xi's view also created a division between moral knowledge and action which Wang insisted was both wrong and pernicious. Wang's response to Zhu on this issue resulted in his most well-known teaching: the unity of knowledge and action.

Wang relied upon the distinction, first developed by Cheng Yi, between 'real knowledge' and 'ordinary knowledge' to argue that anyone who really knew any moral truth must necessarily act upon it. Such action was a necessary constituent of real knowledge. One actually had to engage in filial activity in order to know what filial piety really is, and all those who possessed such knowledge would spontaneously act in accordance with their knowledge when faced with an appropriate situation. People who claim to know filial piety but do not act filially simply do not really know.

Wang saw his approach as addressing the most severe consequence of the Cheng-Zhu view. Wang believed that Zhu Xi's approach led people to regard moral self-cultivation as one thing and the affairs of their lives as another. Wang saw Zhu as counselling people to study the classics and calm themselves through quiet sitting in order to improve themselves morally, and then go out and face the world. Wang insisted that this could never work. First, like Lu and Chen before him, he insisted that the moral problems we face are extremely context-sensitive; no

appeal to precedents or rules of conduct can provide us with the guidance we need. As Wang was fond of pointing out, the sages had no such precedents when they acted.

Wang's deeper objection concerned the efficacy of Zhu Xi's method of self-cultivation. Wang did not believe that studying moral theory or contemplating moral paradigms contributed to one's moral development. Such pursuits often had the exact opposite result, for they easily became sources of additional selfish thoughts. In order to improve oneself morally, one needed to work on the actual moral problems of one's own life. Only these engaged one both cognitively and affectively, and only solving such 'real' problems would result in moral improvement.

This antinomian aspect of Wang's thought opened up moral self-cultivation to a much wider range of people, for one no longer needed to be a highly-educated intellectual to grasp the true meaning of the classics (in fact, such an approach would actually lead one farther from self-cultivation). It also gave to his thought an existential flavour; one was made profoundly aware of the weight of one's individual responsibility for one's own moral well-being. The anxiety of such an awareness may even have been critical to gaining true moral understanding. However, Wang's 'existentialism' differs in significant ways from most of its Western advocates. Unlike Kierkegaard, Wang held 'God' to be within each individual and reflected in every feature of the universe; unlike Sartre, existence for Wang does not precede essence for they are one and the same: the mind *is* principle. Properly cultivated individuals faced with similar situations would render similar judgments.

The idea that the mind itself is *li* led Wang to one of his most controversial teachings, known as the Four Sentence Teaching. In his *Chuanxilu (Instructions for Practical Living)*, he said, 'There is neither good nor bad in the mind itself. Good and bad are the activity of thoughts. To know good and bad is pure knowing. To do good and eliminate bad is *gewu* [correcting one's thoughts]'. The first sentence of this teaching seems to contradict not only the central neo-Confucian belief in the innate goodness of the mind, but also Wang's own claims about *liangzhi*. Perhaps Wang is saying that in itself the mind, being the sum of all the principles in the world, is simply how things are in their natural state. In such a state the predicates good and bad are simply inappropriate; they apply only in cases where there is an agent striving either to do good or bad actions. But the mind in itself has no intentions; it just is as it is. Similarly, the people who attain the highest state of moral self-cultivation are not aware that they are doing good. Those who have such thoughts are still striving for goodness and run the risk of becoming 'obscured' by selfish attachment to their own moral progress. The actions of sages, on the other hand, simply happen *through* them. Thus while the actions that result from the fully cultivated mind (that is, the mind itself) will all be good when seen from the perspective of those who observe them, the mind itself is neither good nor bad. Even to say that what the mind does is good is to view its actions from the perspective of the unenlightened. While this view of things profoundly diminishes a person's sense of individual agency, it also lends to their actions a remarkable feeling of necessity.

In the closing years of the Ming dynasty, Wang's ideas - in particular the Four Sentence Teaching - were interpreted by several of his later followers as warranting idiosyncratic judgments of right and wrong. Several of these followers became quite controversial, and a few even died in prison. Later neo-Confucians were to blame these individuals and, by implication, Wang himself for the eventual downfall of the dynasty. While such claims are clearly absurd, they do reveal the perception among the educated elite that the more radical of Wang's later followers showed a degree of independence that many found uncomfortable if not dangerous. These thinkers threatened the order and hierarchy characteristic of Confucian society and advocated such 'radical' ideas as the intellectual and moral equality of women. With the fall of the Ming, these ideas and the intellectual tendencies that gave rise to them came to a halt in a general and dramatic reaction against what was viewed as the Song-Ming drift into radical subjectivism. In its place emerged a movement that again called for a return to 'true' Confucianism based upon a solid 'objective' approach to the classics.

10 The Qing dynasty (1644-1911)

When the Manchus conquered China and established the Qing Dynasty, Chinese intellectuals once more found themselves facing the problem of how to explain the failure of the Confucian Way. Again, their answer was that the Way had been misunderstood and poorly practised. So began a prolonged and wide-ranging attack on the whole of the neo-Confucian tradition, from the Song through the Ming. One of the first and most important figures in this new movement was Wang Fuzhi.

Wang attacked both the Cheng-Zhu and Lu-Wang schools. Most of his objections turn on his rejection of their basic metaphysical schemes. He insisted that there was no *li* ('pattern' or 'principle') apart from *qi* (ether). *Li* is simply the 'pattern' of 'actual things and events'. Wang rejected the notion that there exists something called the *taiji* or anything like it which is the sum of all *li* and the related claim that all things somehow reflect all the *li* in the world. This of course meant that he also rejected the Lu-Wang school's equation of principle and mind. He believed that both schools tended to reify *li*, turning people's attention away from the actual things and events in the world and towards the search for some fanciful, ultimate *li*. He further believed that this 'other-worldly' speculation was a direct consequence of Daoist and Buddhist corruption of Confucianism and the primary cause of the defeat of the Chinese at the hands of the Manchus.

Wang's views had further quite profound implications. For example, while he admitted that the actual things and events in the world tended to fall into natural types and patterns and are related through an ongoing process of evolution, his strong denial of any ahistorial universal 'principles' and his belief in the steady historical improvement of social institutions and practices led him to advocate quite radical notions of social reform.

The next important figure in the Qing dynasty is Yan Yuan. Like Wang Fuzhi, he rejected both of the Song-Ming Schools. One of his main arguments against the Song Confucians rests upon his claim that they mistook the meaning of the word *wen* (culture), interpreting it instead as 'writing'. The Chinese graph he is referring to appears throughout the classics and can have either of these meanings, but Yan argued that Confucius' primary interest was 'culture'. Song neo-Confucians mistakenly believed that they were following Confucius when they engaged in the extensive writing of commentaries and explanatory essays on the classics. Yan responded by saying that Confucius only engaged in these activities when it became evident that no ruler in his time would employ him and put the Way into practice. He turned to the task of preserving the *dao* only when faced with this intractable fate; and he did so after having mastered the *dao* through years of diligent practice.

Yan advocated a return to the institutions and practices of the sages, and on this issue he differed dramatically from Wang Fuzhi and shows important similarities to Xunzi. One should practise the six arts which Confucius had taught: ceremony, music, archery, charioteering, reading and mathematics. Such concrete practice would lead one to sagehood. For Yan, *gewu* was neither the discovery of some underlying 'principle' (Zhu Xi) nor the rectification of one's 'thoughts' (Wang Yangming). It was the task of mastering the skills and abilities of the sages. For Yan, sages were individuals of sound mind, spirit and body: men of action. Yan harshly criticized the Confucians of his day for being effeminate and ineffective intellectuals, and he saw their personal moral failure manifested in the defeat of the Chinese state. Like many Confucians, Yan believed that those who were really following the Way could not but create a flourishing, peaceful and strong society. At times he almost seems to be arguing for a kind of pragmatism. However, what appears as a 'pragmatic' appeal is the widely held Confucian belief in the efficacy of the Way. In the face of defeat at the hands of the Manchus, Yan's natural response was that his predecessors had lost the true Way.

11 The Qing dynasty (1644-1911) (cont.)

The greatest philosopher of the Qing dynasty was Dai Zhen. Dai had a lifelong dedication to philosophy, but until recently was not appreciated for his philosophical contributions. He was however a highly respected mathematician, geographer, astronomer and philologist. This is largely a result of the particular *Zeitgeist* of the Qing, which had a profound appreciation of 'hard sciences' such as textual study and little tolerance for speculative philosophy. Ahead of his time, Dai denied this distinction.

One can gain a significant insight into Dai's views by studying the form of his two major philosophical works: the *Yuanshan (On the Good)* and the *Mengzi ziyi shuzheng (The Meaning of Terms in the Mencius Explained and Verified)*. Both of these are works of philosophical philology, commentaries on the meaning of key philosophical terms taken from the Confucian classics, which argue against common interpretations and provide both argument and philological evidence for a new view. Since Dai believed that the classics were the key to understanding the *dao*, his philosophical method necessarily contained a strong philological component. For one cannot understand the classics without understanding the words of these texts, and only sound philological method allows one to do this. On the other hand, Dai insisted that philological inquiry only had value when employed in the service of philosophy, for all inquiry should be directed towards an understanding of the *dao*.

His philological method reflects or perhaps more accurately prefigures his philosophical views. Dai believed one clearly cannot rely upon raw intuition in deciding the meaning of a term; one must resort to careful study of its uses throughout the classics. As one refines one's initial theory in the light of different cases, one moves closer to the correct meaning, the one that accounts for all the cases. This approach is clearly manifested in the two works cited above, where he provides extensive evidence to argue against both the Cheng-Zhu and Lu-Wang interpretations of the key terms of Confucian philosophy. Dai convincingly demonstrates how the interpretations of both schools are not attested in the classical sources and further argues for their Daoist and Buddhist origins. Both the Cheng-Zhu and Lu-Wang schools were overly subjective in the sense that they read into the classical texts their own personal views. This is one example of a general type of error that was the focus of much of Dai's attention.

For Dai, the most common error people make is to mistake their private 'opinions' (*yijian*) as 'unchanging standards' (*buyi zhize*). This applies to determining the meaning of a philosophical term as well as to making an ethical judgment; for Dai, these were but two sides of a very thin coin. In the case of ethical standards, one moved from 'opinion' to 'unchanging standard' by applying the Confucian Golden Rule: not doing to others what one would not want done to oneself (see Confucius). This mirrors the logic of moving from one's initial impression of what a term means to the correct interpretation: both involve a progression from personal opinion to a comprehensive or universal view. In the specific case of ethical judgments, Dai believed that this movement led one from what is 'spontaneous' (*ziran*) to what is 'necessary' (*biran*). That is, one begins with one's spontaneous reaction to a situation and, through an appeal to the Golden Rule, tests this reaction to see if it passes muster as a universal standard. If it does then the reaction is certified as 'correct', something that one 'necessarily' must do. If it fails this test, it is revealed as merely one's own selfish 'opinion' (see Confucian philosophy, Chinese).

Dai offered a remarkably novel and powerful interpretation of the Confucian vision. He is rare if not unique among Confucians for his strongly rational and intellectualist approach towards moral self-cultivation. Yet, while he provided compelling criticisms of the Daoist and Buddhist elements within earlier neo-Confucian thought, he himself was not without such influences. Unlike early Confucians who believed that one needed to acquire or at least extend and expand one's moral sensibility, Dai seems to have held that one already possesses the ability to make proper moral judgments. The problem for him is not that we lack the proper sense, but rather that we also have many improper reactions that must be identified and eliminated.

It is tempting to see Dai as one step away from a kind of Kantian view of ethics with his appeal to a type of universalizability criterion (see Kant, I.), but this would be to misrepresent Dai's thought. For one thing, he believed in an inextricable link between philosophy and philology: one could not find ethical truth apart from understanding of the classics. Dai did not see the Confucian Golden Rule (itself an idea derived from the classics) as free-standing; it did not generate all and only correct ethical judgments. It was a winnowing process to determine which among our spontaneous reactions were in fact in accord with the *dao*. These reactions were feelings about the rightness or wrongness of a given act, and if they were found to be genuine 'necessary' moral feelings, then this recognition produced a profound feeling of joy within the individual. Dai was very much a Confucian defending his tradition.

12 Conclusion

This survey of neo-Confucian thinkers is necessarily selective in terms of the figures covered. It also is confined to what might be called pre-modern philosophers. In the closing period of the Qing dynasty several extremely interesting and innovative thinkers such as Kang Youwei, Tan Sitong and, in the twentieth century, Feng Yulan produced new versions of Confucian philosophy which incorporated and synthesized their understanding of Western philosophy, religion and science. These new forms of Confucian thought continue to be developed in contemporary times, but as they represent a new and distinct stage in the Confucian tradition, they warrant a separate and detailed study in their own right.

Neo-Kantianism

In contrast to earlier research, which chose to distinguish up to seven schools of thought within the field of Neo-Kantianism, more recent scholarship takes two basic movements as its starting point: the Marburg School and the Southwest German School, which are based respectively on systematically oriented works on Kant published during the 1870s and 1880s by Hermann Cohen and Wilhelm Windelband.

Cohen held that Kant's concern in all three Critiques was to reveal those a priori moments which above all give rise to the domains of scientific experience, morality and aesthetics. Windelband on the other hand held that Kant's achievement lay in the attempt to create a critical science of norms which, instead of giving a genetic explanation of the norms of logic, morality and aesthetics, aimed instead to elucidate their validity. In both approaches, an initial phase during which Kant's doctrines were appropriated subsequently developed into the production of systems. Thus Cohen published a 'System of Philosophy' during the early years of the twentieth century, which consisted of the Logik der reinen Erkenntnis (Logic of Pure Knowledge) (1902), the Ethik des reinen Willens (Ethics of Pure Will) (1904) and the Ästhetik des reinen Gefühls (Aesthetics of Pure Feeling) (1912) and which radicalized the operative approach of his work on Kant. Later, Cohen conceived a Religion der Vernunft aus den Quellen des Judentums (Religion of Reason from the Sources of Judaism) (1919). Windelband, on the other hand, who made a name for himself primarily in the sphere of the history of philosophy, understood philosophy to be essentially concerned with value, anchored in transcendental consciousness. He emphatically linked the classical division of philosophy into logic, ethics and aesthetics to the values of Truth, Goodness and Beauty and also tried to situate the philosophy of religion in this context.

Apart from Cohen, the Marburg School is represented by Paul Natorp and Ernst Cassirer, whose early works followed Cohen's philosophical views (compare Natorp's interpretation of the Platonic doctrine of ideas and Cassirer's history of the problem of knowledge), but whose later works modified his approach. Nevertheless, their extensions and developments can also be explained within the framework of the original Marburg doctrines. The ontological turn which Natorp undertook in his later years can be seen as a radicalization of Cohen's principle of origin, which Natorp believed could not be expressed in terms of pure intellectual positing, and the operative moment introduced by Cohen lives on as a theory of creative formation in Cassirer's theory of symbolic forms.

In addition to Windelband, the Southwest German school of Neo-Kantianism is represented by Heinrich Rickert, Emil Lask, Jonas Cohn and Bruno Bauch. Windelband instigated the systematic approach of the Southwest School, but it was left to Rickert to develop it fully. Unlike Windelband, who traced the difference between history and science back to the difference between the idiographic and the nomothetic methods, Rickert distinguished between the individualizing concepts of history and the generalizing concepts of science. During his middle period he turned his attention to the problem of articulating a system of values. In his later works, Rickert also turned towards ontology, a development which should not necessarily be interpreted as a break with the constitutional theories of his early years. In concrete terms, building on his earlier theories concerning the constitutive role of concepts in experience, Rickert henceforth distinguishes not only the realm of scientific and cultural objects and the sphere of values, but also the further ontological domains of the world of the free subject and the metaphysical world, which is the object of faith and which can only be comprehended by thinking in symbols.

Lask's theoretical philosophy was characterized by a turn to objectivism. In contrast to the classical Neo-Kantian conception of knowledge, according to which everything given is determined by the forms of cognition, Lask sees matter as that element which determines meaning. Accordingly, at the centre of his theory of knowledge is not the subject's activity in constituting the object, but the subject's openness to the object. In the final stage of his philosophy, however, he once more attributed to the subject an autonomous role in the actualization of knowledge. Cohn contributed to Southwest German Neo-Kantianism not only his Allgemeine Ästhetik (General Theory of Aesthetics) (1901), but also works on the philosophy of culture and education as well as on the systematic articulation of values and the problem of reality. During the 1920s Cohn moved towards dialectics. In contrast to Hegel, however, he understood this to mean critical dialectics inasmuch as it does not aim to sublate or overcome opposition, but merely sets itself the unending task of attempting to resolve irreconcilable contradictions.

Finally, Bauch can be regarded as the most essentially synthetic thinker of the Southwest German Neo-Kantian school. He tried to demonstrate the inseparable connectedness of individual problems which had generally been

treated separately. Apart from his great Kantian monographs, these ideas are also put forward in his systematic works on the questions of theoretical and practical philosophy, such as his study Wahrheit, Wert und Wirklichkeit (Truth, Value and Reality) (1923) and his Grundzüge der Ethik (Fundamentals of Ethics) (1935).

Despite the one-sidedness of its reception of Kant's doctrines, Neo-Kantianism was important for the momentum it gave to research into Kantian philosophy during the twentieth century. Its systematic achievement lies in its development of the normative concept of validity and its programmatic outline for a philosophy of culture.

1 Delimitations and affiliations

The term 'Neo-Kantianism' arose in the 1870s and owes its origins to the need to characterize that overall reassessment of the theories of Immanuel Kant which was then taking place in various different forms. The terminological problem concerns how broadly or narrowly the expression should be applied. Earlier research tended to work with definitions which encompassed ever-increasing circles. Thus T.K. Oesterreich claimed to distinguish seven different approaches to Neo-Kantianism: a physiological approach (of Hermann von Helmholtz and Friedrich Albert Lange), a metaphysical approach (of Otto Liebmann and Johannes Volkelt), a realistic approach (of Alois Riehl), a logicist approach (of Hermann Cohen, Paul Natorp and Ernst Cassirer), an approach based on a theory of values (of Wilhelm Windelband and Heinrich Rickert), a relativist approach (of Georg Simmel) and a psychological approach (of Leonhard Nelson). This classification is problematic for a number of reasons. Not only is it doubtful whether Simmel and Nelson should be included among the Neo-Kantians in the first place; it is also questionable whether the specific attitudes of Lange's particular understanding of Kant justifies his inclusion among the supporters of the physiological approach. Furthermore, it is unfortunate that, in the chronological list of the individual approaches, the metaphysical approach of Liebmann is listed before the logicist Neo-Kantians, for Liebmann's turn towards a metaphysical approach came after the beginning of the Marburg School, which based its theories on a logicist approach. Finally, this list gives no mention of the representatives of the philological approach to the doctrines of Kant. More recent research has moved away from comprehensive definitions of this nature and now distinguishes between the Marburg School and the Southwest German School of Neo-Kantianism, and a Kantian movement which extends beyond these limitations. The latter movement did not remain confined to Germany but could also be found in other European countries such as France (in the philosophy of Charles Renouvier) or Italy (with Carlo Cantoni), where it demonstrated its debt to Kant in a variety of ways.

Even if we accept that Neo-Kantianism is restricted to these two main schools, we must ask which writers should be ascribed to which school. To all intents and purposes, the Marburg School is limited to Cohen and Natorp and the Southwest German School to Windelband, Rickert and Emil Lask. However, should one include among the Neo-Kantians Cassirer in his middle and later periods along with Jonas Cohn and Bruno Bauch, though they are both writers whose important works were mostly published after the First World War? There is no consensus among Neo-Kantian scholars on this point. Some writers operate with a very narrow definition of Neo-Kantianism, while others apply the term in a much wider sense. The representatives of the first position argue that the First World War marked the end of the Neo-Kantian movement. Therefore they take all publications which appeared after the end of the First World War and illustrated a Neo-Kantian approach as in one way or another influenced by Neo-Kantian thought. The scholars who adopt a wider definition of Neo-Kantianism distinguish on the other hand between first- and second-generation Neo-Kantianism and assume in this context that Neo-Kantianism did not simply come to an end after the First World War. The first approach is supported by the fact that the First World War did also represent the end of an era in the philosophical world. After 1918 other philosophical trends gained ground and forced Neo-Kantianism out of the dominant position which it had enjoyed since the late nineteenth and early twentieth century, at least in Germany. Significant factors in this respect are the phenomenology of Edmund Husserl, who demonstrated the validity of transcendental thought in a different way from the Neo-Kantians; a logical positivism which challenged Neo-Kantianism on its own ground, in other words, epistemology and theory of science; attempts at a metaphysical interpretation of Kant which then developed; and cultural-critical philosophies of life which dominated public discussion. At the same time, a number of movements set themselves apart from the main trend. Nikolai Hartmann distanced himself from his Neo-Kantian origins in his attempt to re-establish an ontology, as did Martin Heidegger in his attempt to find a solution to the question of being. Richard Kroner, a pupil of Rickert, consciously made the transition to Neo-Hegelianism (see Hegelianism §6). However, if one considers not only the changed background conditions but also the internal theoretical

development within both schools, it will become clear that the second position also has good arguments to support it. For it cannot be maintained that the followers of the Neo-Kantian school failed to react to the changes in philosophical climate as a whole. This is shown not only in the later works of Natorp and Rickert: the philosophical thought of Cassirer, Bauch and Cohn must also be interpreted in the light of this approach. It is clear that these developments in the growth of the theory are just as much a part of the history of Neo-Kantianism as the phase of theoretical systems produced before the First World War. For this reason, this extended definition of Neo-Kantianism will be taken as the starting point for the following discussion.

Cohen, Natorp and Cassirer, on the one hand, and Windelband, Rickert, Lask, Bauch and Cohn, on the other, are merely the most important representatives of Neo-Kantianism. Apart from them, a large number of other philosophers can be included among the followers of both main trends, or at least associated with them. Earlier research assumed a close-knit school containing the various proponents of these doctrines; more recent approaches, however, have been more cautious in this respect. As far as Marburg Neo-Kantianism is concerned, it is possible to distinguish between a group of scholars closely associated with Cohen, including - apart from Natorp and Cassirer - Karl Vorländer and Albert Görland, and a wider circle of disciples among whom were Hartmann and Heinz Heimsoeth. None the less, Natorp’s attitude to a term like ‘The Marburg School’ was decidedly ambivalent. Although he accepted this definition for the purposes of academic debate, he wanted it to be understood merely as a term of collaborative association.

The relationships within the Southwest German School of Neo-Kantianism are similar. The labelling of Windelband and Rickert as the two leaders of the school is problematic inasmuch as Windelband had only sketched his systematic position, whereas Rickert must be credited with the true development of the Southwest German system. A circle of disciples also grew up around the latter in Heidelberg, among whom were Eugen Herrigel and Hermann Glockner. Furthermore, as in the case of Marburg Neo-Kantianism, a whole series of writers, such as Georg Lukács and Max Weber, found important inspiration in the philosophy of Southwest German Neo-Kantianism. There are also links with the work of Gottlob Frege. Finally, of considerable significance for the spread of Southwest German Neo-Kantianism was the fact that the periodical *Logos* provided a publication outlet from 1910.

For an understanding of Neo-Kantianism it is important to recall that the discussion of specifically Neo-Kantian ideas also continued outside the framework of the Marburg and Southwest German approaches. Riehl’s pupil Richard Hönigswald adopted, on the one hand, a critical approach to the Neo-Kantian logic of scientific method, because in his eyes the latter was based upon an undifferentiated concept of experience and pursued a different path from the Neo-Kantian approach to subjectivity by projecting a theory of the concrete subject within the context of his philosophical psychology. On the other hand, he continued to endorse the Neo-Kantian concept of normative validity, even though he attempted to develop this concept further in terms of a novel theory concerning the differentiation of spheres of validity.

Hönigswald, moreover, like his Jewish colleagues Cohn and Cassirer, was deprived of his professorial chair and had to emigrate after Hitler’s rise to power. The expulsion of the leading representatives of Neo-Kantianism from German universities was mainly responsible for bringing to a halt philosophical research into the problems posed within the Neo-Kantian doctrines, and the Second World War exacerbated this situation. In the post-war development of German philosophy only a few philosophers, such as Wolfgang Cramer, Hans Wagner and Rudolf Zocher, chose to continue in this theoretical tradition.

2 The origins of Neo-Kantianism

In earlier research the overriding tendency was to trace Neo-Kantianism back to certain founding figures. Thus, for example, the role of inaugurator of the Neo-Kantian movement was attributed to Liebmann. This view was based mainly on his early work *Kant und die Epigonen (Kant and the Epigones)* (1865), in which he had accused all branches of post-Kantian philosophy of working with a variously interpreted notion of the thing-in-itself. In the true Kantian view this was a false approach, and in each case he concluded his criticism of the schools of idealism (Fichte, Schelling, Hegel), realism (Herbart), empiricism (Fries) and transcendentalism (Schopenhauer) with a demand that scholars should return to Kant. In the same way, Helmholtz and Lange were credited with having founded the Neo-Kantian movement, since they both based their doctrines on the Kantian a priori, which they admittedly (mis)interpreted in terms of innate species-specific capacities (*Gattungsorganisation*), turning their

backs on the simplistic objectivism popular during the 1850s in the context of the debate concerning materialism. Finally, Eduard Zeller was also frequently associated with the origins of Neo-Kantianism. In his lecture *Über die Bedeutung und Aufgabe der Erkenntnistheorie (On the Meaning and Purpose of the Theory of Knowledge)* (1877) he was the first philosopher to win academic acceptance for epistemology or the theory of knowledge, which played a central role within the framework of the Neo-Kantian system.

Modern research sees the birth of Neo-Kantianism as being more clearly determined by certain developments which were characteristic of the philosophy of the post-Hegelian period. In the first instance a central role was played by a departure from pure thought and from the systematic philosophy (*Systemphilosophie*) of the idealist tradition, as exemplified in the works of Friedrich Schleiermacher or Adolf Trendelenburg. The latter are important for the development of Neo-Kantianism, first because the concept of theory of science is articulated as early as the second edition of Trendelenburg's *Logische Untersuchungen (Logical Investigations)* (1840), and second because with his *Dialektik (Lectures on Dialectics)* (1839) Schleiermacher can be regarded as the originator of the theory of knowledge. Furthermore, the thesis that German philosophy from Fichte to Hegel pursued a mistaken course which could only be corrected by establishing a direct link with the Kantian tradition was not first formulated by Liebmann, but can be found in the earlier doctrines of Christian Weisse and Friedrich Beneke. A third problem area in post-Hegelian philosophy is the relationship between philosophy and the individual sciences. The attempts by Helmholtz and Lange to provide Kant's theory of knowledge with a sensory-physiological basis against the background of reinstating cooperation between philosophy and science was just one way of overcoming the problem. There was also the opposite tendency, which aimed at rejecting the inclusion of individual and special scientific knowledge in an attempt to maintain the autonomy of philosophy. This attitude can be found in the works of Kuno Fischer, Liebmann's teacher, who propagated a neo-idealistic interpretation of Kant in the manner of Fichte and played an important role in the foundation of Southwest German Neo-Kantianism. Fourth, in addition to the critical approach to the idealist point of view there was also the tendency to insist on the necessity for a critique of knowledge in the hope that it would finally provide a means of settling disputes about fundamental questions of worldview or '*Weltanschauung*'. Such a tendency is to be found not only in the works of Zeller and Lange, but also in the those of J.B. Meyer, a hitherto largely unknown philosopher in the field of Neo-Kantian research. In his essay *Über Sinn und Wert des Kritizismus (On the Meaning of Criticism)* (1857), Meyer emphasizes that the relationship between body and soul belongs, like all metaphysical questions, to those problems which transcend the horizon of our possible knowledge, and that the significance of '*kritizistischen Kant*' ('Kant the Criticist') lay in the way in which he had demonstrated this fact. Similarly, in his programmatic deliberations concerning the theory of knowledge, Zeller repudiated the exploitation of specific, scientific knowledge for the purpose of establishing a worldview, just as Lange was eventually concerned to refuse universal claims based on such a worldview, of whatever kind they were.

Therefore, even if the extensive pre-history of the Kantian movement is taken into account, there can be no doubt that its real breakthrough occurred during the 1870s and 1880s. In 1871 Cohen published his work *Kants Theorie der Erfahrung (Kant's Theory of Experience)*, which set out to establish Kant's doctrine of the a priori. Cohen's central thesis is that only those things can be seen to be objective which are produced a priori by subjectivity. Thus he understands Kant's *Critique of Pure Reason* to be a theory of experience in which Kant's aim was to reveal those a priori moments which make scientific experience possible. In the same vein he maintains that in ethics and aesthetics Kant was also concerned with the revelation of those a priori elements which in the first instance generate the sphere of morality and art. This concept of generation thus provided the basis for a new form of systematic appropriation of Kant which was significantly different from the subjective-idealistic Kant interpretation of Kuno Fischer or Lange's naturalistic interpretation. Cohen considers both interpretations inadequate because neither manages to provide a stable basis for the sphere of the ideal. In the case of Lange in particular, Cohen criticized the fact that, although he attempted in his *Geschichte des Materialismus* (*History of Materialism*) to save ethics in opposition to the mechanistic-deterministic worldview, he nevertheless failed to justify the idealist point of view in a scientific manner. Cohen believed that he had found the means of achieving this in his concept of generation. In his view, modern natural science is the best evidence for the fact that reality as objective has been created by us, since we are only capable of knowing that which we have put into things.

This realist attitude was given a different emphasis in the Kantian research of Friedrich Paulsen and Alois Riehl. Paulsen's *Versuch einer Entwicklungsgeschichte der Kantischen Erkenntnistheorie (Attempt at a History of the*

Development of Kant's Theory of Knowledge) (1875) aims, as the title indicates, at a historical and systematic reconstruction and not, like Cohen's work, at a new and improved presentation of Kant's doctrine of the a priori. Thus Paulsen's goal was not a productive assimilation of Kantian thought against a background of the specifically nineteenth-century conflict between idealism and materialism, but an attempt to understand the philosophy of Kant from its historical context, against a background of the contrast between rationalism and empiricism during the eighteenth century. Riehl's three-volume work *Der philosophische Kritizismus und seine Bedeutung für die positive Wissenschaft (Philosophical Criticism and its Significance for Positive Science)* (1876-7) aimed to place Kant within a tradition of critical thought which began with John Locke. In his view, Kant's critical position tends towards a 'Phenomenalism of Intuitions' which is at the same time a 'Realism of Things'. Riehl regarded the epistemological scepticism represented by David Hume as the precursor of such a position, since it can be seen as a means of securing a positive content for thought. Thus, in his presentation of Kant, Riehl undertakes an attempt to bridge the gap between Kantianism and positivism. This approach can also be seen in his history of philosophy, which assumes as its basic concept a parallelism between scientific and philosophical history. Benno Erdmann completes the spectrum of Kant interpretations during this period. His works use a purely historical approach to reconstruction and rejected all attempts to update Kantian thought.

Finally, during this period Windelband founded the Kantian approach of the Southwest German School, and this represents a second type of systematic Kantian assimilation beside that of Cohen. Mindful of the overwhelming significance of Kant for all subsequent philosophical endeavours, Windelband investigates the nature of the critical method put forward by Kant. According to him, what is essential in this respect is the contrast with every type of genetic method. Unlike the genetic method, it is not a question of explaining how certain norms in the realm of logic, ethics and aesthetics were established. Instead, Windelband's critical method questions the correctness of the norms that have come into existence in these areas. In other words, its aim is the clarification of the question of justification. Windelband is convinced that Kant and his three Critiques made a significant contribution to the critical science of norms. Thus philosophy, if it wishes to counter the relativism which inevitably results from a consistent application of the genetic method, is obliged to return to Kant. At the same time, however, Windelband emphasizes that such a 'return' to Kant cannot involve simply a revival of the historically conditioned form of his philosophy, but remains a task for all contemporary engagement with the philosopher from Königsberg: to understand Kant means to go beyond him.

3 The Marburg School: Cohen

Cohen's three-part philosophical system serves as a paradigm for the development of the Marburg School system. It consists of the *Logik der reinen Erkenntnis (Logic of Pure Knowledge)* (1902), the *Ethik des reinen Willens (Ethics of Pure Will)* (1904) and the *Ästhetik des reinen Gefühls (Aesthetics of Pure Feeling)* (1912) and attempts to demonstrate in a consistent manner the point of view of pure generation, that is, creation which does not make appeal to any particular preconceptions.

This is particularly clear in the *Logik*, which forms the first part of his system. Cohen differs markedly from Kant in refusing to preface his logic with a doctrine of sensibility. Indeed, his attempt at logic can be characterized by the claim, 'We take thought as our starting point. Thought cannot have any origin outside itself.' According to the 'Logic of Origin' as conceived by Cohen, therefore, thought is grounded solely in itself and is thus a hypothesis in the original Greek sense. The denial of the Kantian theorem of the dual origin of knowledge (intuition and thought) results in the abandonment not only of the transcendental aesthetic as a doctrine of the principles of sensibility, but also of the transcendental deduction (see Kant, I. §§5-6). What remains of Kant's approach is no more than the programme of a transcendental method for the foundation of science, which is obliged to take the existence of science as its starting point. In his doctrine of judgment Cohen differentiates between judgments involving the laws of thought (Origin, Identity, Contradiction), of mathematics (Reality, Plurality, Totality), of mathematical natural science (Substance, Law and Concept) and of method (Possibility, Reality, Necessity). In his doctrine of categories, he starts from the necessary incompleteness and essential extendibility of the system of categories, since he is convinced that new scientific problems will also make new categories necessary.

Cohen sees ethics, which he seeks to base on the fact that a science of right exists, as a doctrine of humanity. The ideal collective subject which ethics deals with is humankind as a whole. It is important that this term is not taken to mean the human species in a biological sense, but rather an ethical expression encompassing humans as moral

individuals. Such an interpretation of the concepts of universality also permits a new definition of the concept for the individual as the idea of the human being in every person. However, the medium which allows us to establish a correlation between these two concepts is the state. For within the state the common will can be realized through the harmony achieved between the actions of the individual and the actions of everyone else. The model of the state which Cohen takes as the basis for his discussion has a cooperative constitution. The essential characteristic of cooperatives is that the common will is legally capable of action. This distinguishes it from communities which only recognize the ruling will of the individual. Against this background Cohen developed the concept of an ethical socialism which aims at overcoming the existing 'state dominated by the estates and the ruling classes' (Cohen 1904: 582), without deteriorating, like the materialist historical perspective, into economic determinism.

In *Ästhetik*, Cohen modifies his system, no longer linking aesthetics back to the fact of an existing science of art, but rather attempting to deduce the a priori law-like character of pure feeling directly from works of art. In doing so he specifically defines pure feeling itself as the feeling of love towards human nature. This is the presupposition not only of the creation of art but also of its reception. With regard to the objectivity of aesthetic experience, Cohen emphasizes that although there are no further objects as such apart from nature and morality, it is possible for the aesthetic orientation of consciousness to shape and transform these spheres of objectivity and thus 'bring forth beauty as a new object' (Cohen 1899: 100).

It is a feature of Cohen's development that during his later years he devoted much of his attention to questions concerning the philosophy of religion. Although during his Marburg years he had argued for the incorporation of religion into ethics, he later recognized that religion also makes a special contribution to the problem of culture. In his essay *Der Begriff der Religion im System der Philosophie (The Concept of Religion in the Philosophical System)* (1915) he attempts to determine this contribution on the basis of the three systematic disciplines of logic, ethics and aesthetics. If logic is concerned with the being of nature, then religion is concerned with the unique being of God, and if the God of ethics stands for the endless continuation of the moral tasks of the human race, then the God of religion must ensure that the moral striving of the individual does not ultimately come to nothing. If aesthetic love is related to humankind as a type, then religious love embraces the human being as individual. Irrespective of this special contribution to culture in its entirety which is accomplished by religion, the latter is not regarded as being independent of culture, but rather as possessing a special character within the framework of culture as a whole. The quest for a non-reductionist understanding of religion is also one of the dominant themes in Cohen's posthumous work *Religion der Vernunft aus den Quellen des Judentums* (*Religion of Reason out of the Sources of Judaism*) (1919). It cannot be said, however, that Cohen achieved a position of ultimate clarity with regard to religion. Evidence for this can be found, for example, in the interpretative dispute concerning an idealistic or dialogical interpretation of the term 'correlation', which plays a central role in Cohen's later philosophy of religion. Is Cohen envisaging simply a relationship between two concepts which are mutually required (in much the same way as the concept of the sinful individual necessarily calls for the concept of God, who forgives sins), or does he have in mind a real contrast of two partners as is suggested by the definition of prayer as 'dialogue with God'? Furthermore, there is a tension in Cohen's posthumous work between the ethically orientated interpretation of the religious statements which he attempts to provide and the simultaneous reversion to statements reflecting a metaphysical doctrine of divinity. On the one hand he states that the doctrine of divine attributes should not be interpreted in terms of ontological statements about God, but rather in terms of statements which make clear how human behaviour should be governed. On the other hand, Cohen characterizes God as the one and only unique Being as opposed to all Becoming, as the Infinite as opposed to all spatial limitations, as the source of all movement, and as the Eternal in contrast to all Change. Cohen was unable to carry out his plans for a fourth work to complete his 'System of Philosophy', a psychology conceived on a science of the unity of cultural consciousness.

4 The Marburg School: Natorp

Natorp was able to present his thoughts in a clearer and more comprehensible form than Cohen, and hence he was largely responsible for the spread of the doctrines of the Marburg School of Neo-Kantianism. Unlike Cohen, he is not famous for a comprehensive range of studies on Kant. None the less, he also made a name for himself by virtue of his works on the history of philosophy. Of greatest relevance in this context is his controversial and subsequently modified interpretation of Plato, in which he understood the Platonic 'idea' as a hypothesis from the perspective of the modern concept of the laws of nature.

In his systematic thought, Natorp at first operated systematically within the terms laid down by Cohen. None the less, even in *Kant und die Marburger Schule (Kant and the Marburg School)* (1912a) he emphasized that philosophy did not merely refer back to scientific facts (natural sciences and humanities) but was also related fundamentally to morality, art and religion. Its subject is therefore 'the entire creative work of culture', which is expressed in the 'theoretical-scientific description of phenomenal appearance' as well as in the 'practical formation of social orders', 'in artistic creativity' and 'in the inmost forms… of religious life'.

In his *Allgemeine Psychologie nach kritischer Methode (General Psychology According to the Critical Method)* (1912b) Natorp goes further than Cohen in setting a subjective foundation for knowledge alongside the objective one. He is guided by the following consideration: in every phenomenal appearance we can differentiate between a relationship to the object and a relationship to our consciousness. The former is the subject matter of the theory of knowledge which establishes the laws of cognitive objectification; the latter is the subject matter of psychology, which proceeds back to the objective phenomenon of knowledge from the already accomplished objectifications, since the 'immediacy of consciousness' does not permit any immediate psychological comprehension.

In his doctrine of knowledge, Natorp attempts to interpret Cohen's concept of origin in the context of Kant's synthetic unity. According to this theory, that which characterizes the thinking process is the basic structure of the relation between the one and the many. In this fundamental relation there are two tendencies: a differentiating tendency, which aims at quantity, and a unifying tendency, which aims at quality. Quantity results when the manifold as such is emphasized in the fundamental relation; quality results, on the other hand, when thought is directed towards the unity of the manifold. The relation arises with the establishment of interdependency between the unities, which are determined in a quantitative-qualitative manner, whereby the modality determines the contribution of each level of the 'thought-functions' constituting the object to the knowledge of that object. In contrast to Cohen, Natorp does not base this system of fundamental logical functions on a system of sciences, although he asserts that the systematic logical structure it contains will prove its validity in the fact that the basic scientific facts can be connected with the logical ones. In fact, Natorp starts out from a reciprocal interrelationship between science and the logic of knowing. While the latter tends towards the centre, in other words towards the basic law of synthetic unity, the former tends towards the periphery, that is, the manifold diversity of the particular instances of knowledge. The difference between this and Cohen's position also becomes clear since, for Natorp, the reason belonging to science proves itself in the foundation of the objective sciences from the perspective of synthetic unity, while for Cohen reason proves itself in demonstrating the origin of all knowledge out of pure thought.

Natorp's social educational theories, which he developed after becoming professor of philosophy and education in Marburg, were very influential. The subtitle of *Sozialpädagogik* (1899), his major work on the subject, is *Theorie der Willenserziehung auf der Grundlage der Gemeinschaft (Theory of the Formation of Will on the Basis of the Community)*: it makes clear that Natorp sees the formation of will as the most important aspect of education, particularly inasmuch as the former is determined by life within the community and has an effect on the community. In the development of will Natorp distinguishes three stages of activity: instinct, will and the rational will. Whereas instinct is wholly governed by the sensory object, will on the other hand provides for the possibility of choice in this respect. True moral orientation, however, occurs only in the case of the rational will. Although a restructuring of society in accordance with the principles of ethical socialism implies changes within its economic and political institutions, Natorp none the less sees the real motor for change in the sphere of social education, since only education can bring about a change of consciousness.

At the heart of Natorp's later philosophy stands his attempt at a new definition of the doctrine of categories, whose goal is a unified foundation of every kind of positing of an object ('*Gegenstandssetzung*'). Natorp starts concretely with a closed system of basic categories - modality, relation and individuation - which are to serve as the basis for the construction of an open system of categories. By adopting this distinction between categories and basic categories he attempts to do justice both to Kant's assumption of a comprehensible number of basic concepts of understanding and to the fact that the process of investigation means that a number of categories cannot be determined in advance. Natorp's system of basic categories is also built up in a different way from Kant's, inasmuch as he begins here with the categories of modality (Possibility, Necessity and Reality) and places the categories of Quantity, Quality and the intuitive forms of Space and Time in the third group of categories. The second group of categories (Substance, Causation and Interaction) corresponds on the other hand with the original

Kantian architectonic which Natorp had mainly used as a starting point in his early attempt at a system of categories, *Die logischen Grundlagen der exakten Wissenschaften (The Logical Foundations of the Concrete Sciences)* (1910). The order of categories within the individual groups occurs in each case according to the scheme: universality, particularization, individuality. This structure applies not only to the theoretical sphere but also to the practical and what Natorp calls the 'poetic' (that is, productive) spheres. Natorp's later philosophy is characterized by the insight that the process of categorization assumes the acceptance of the as yet totally undetermined original fact of 'it is' and ends with the determination of the individual as the concrete objective existent. This ontological modification of Natorp's late philosophy need not necessarily be interpreted - as it frequently is - as a break with the Marburg theoretical outlook; it can also be seen in terms of a radicalization of the original Marburg theory.

5 The Marburg School: Cassirer

Like Cohen and Natorp, Cassirer, who was Cohen's principal disciple, made a name for himself initially in the history of philosophy. After his doctoral thesis under Cohen on *Leibniz' System in seinen wissenschaftlichen Grundlagen (Leibniz's System in its Scientific Foundations)* (1902), he enjoyed immediate success with the first two volumes of his four-volume *Geschichte des Erkenntnisproblems (History of the Problem of Knowledge)* (1906-20). In it he demonstrated in particular the emergence of a new definition of knowledge during the Renaissance which reached its climax in the philosophy of Kant. Thus Cassirer attempted to make plausible Cohen's claim concerning the harmony of his basic ideas with the historical development of scientific and philosophical thought.

Cassirer also turned his attention to the theory of the exact sciences, publishing his *Substanzbegriff und Funktionsbegriff (The Concept of Substance and the Concept of Function)* (1910) at the same time as Natorp's investigation *Die Logischen Grundlagen der exakten Wissenschaften*. Here, Cassirer makes it plain that any attempt to represent the whole of knowledge ends in certain ultimate form-concepts which express the various possible ways in which contents can be related to one another. In this respect, what we call the object of knowledge is dissolved in a network of relations. What applies to the concept of the object in general is also relevant for the concept of the objects with which the individual sciences operate. They too do not represent an absolute beyond the logical forms of knowledge, but that which is to be expressed through them is nothing but a functional relation within these forms. In concrete terms, Cassirer sees in the serial ordering which manifests itself in the relations of space and time, of size and number and of dynamic interaction and interrelationship of events, the moment in the process of knowledge which determines its real empirical content. The logical determination of the object of knowledge thus leads ultimately to an original relation which can be understood in various ways: as a relation of form and matter, of the universal and particular, and of being or normative validity. What is important is that this relation between reciprocally determining elements remains irreducible. Taken as a whole, what distinguishes Cassirer's concept of knowledge is the insight that concepts are intellectual constructs which cannot be understood as an imitation of the objective given but as 'symbols for relations and functional connections within the real'.

A third major theme in Cassirer's philosophical work is the philosophy of culture. His *Philosophie der symbolischen Formen* (*The Philosophy of Symbolic Forms*) (1923-9) is relevant in this respect. Cassirer understands by the term 'knowledge' not only that mathematical-scientific form of knowledge which remained paradigmatic for the Marburg School, but rather 'any intellectual activity in which we construct a world for ourselves with a characteristic form, order and particular character' (1956: 208). The concept of symbolic form implies on the one hand a formal function, for it is essential that 'an intellectual meaning is attached to a concrete sensory sign and internally allocated to this sign' (1956: 175). On the other hand, Cassirer also marks out in this manner as characteristic areas of such formation, such concrete areas of culture as language, myth, art and science. Although the symbolic activity linked to signs is that activity which runs through all productive achievements of consciousness as a unifying theme, further differentiations with regard to the basic functions of the symbolic form will result. Here Cassirer distinguishes between the function of expression, the function of presentation and the function of meaning. The almost physical function of expression is particularly relevant in the case of myth, the distancing presentation function is the preserve of language, and the function of meaning is found in particular in the world of science. The systematic implications of Cassirer's theory of symbolic forms are further developed in his final works, *An Essay on Man* (1944) and *The Myth of the State* (1946), produced after his emigration to

America.

Like the later works of Natorp, the works of Cassirer's middle and later periods raise the question of whether they should really belong to the Marburg School of Neo-Kantianism. This is a subject of lively debate even today. It is certainly the case that Cassirer's middle and late works transformed Cohen's approach, which revolved around the problem of knowledge and science. Similarly, it cannot be maintained that Cassirer in his later development actually abandoned his Neo-Kantian beginnings, for even in his conception of a philosophy of symbolic forms he retains the typical emphasis upon the generative-theoretical approach characteristic of the Marburg School.

6 The Southwest German School: Windelband

Although the real development of the Southwest German system was the work of Rickert, and Windelband merely sketched his systematic approach in a collection of essays with the descriptive title *Präludien (Preludes)* (1884) as well as in his *Einleitung in die Philosophie (Introduction to Philosophy)* (1914), the importance of Windelband as an initiator is not to be underestimated. Windelband understands philosophy as a whole to be concerned with values. He rejects a purely objectivist conception of value and attempts instead to solve the problem of the objectivity of values in a transcendental manner by having recourse to an archetypal consciousness (*Normalbewußtsein*) which is able to make value judgments, and for which the Kantian 'Pure Consciousness' (*Bewußtsein überhaupt*) serves as a foil. He traces the traditional division of philosophy into the disciplines of logic, ethics and aesthetics back to the way in which these disciplines are orientated to the values of Truth, Goodness and Beauty. Like Cohen, Windelband also attributes a special role to religion. According to him, the sphere of human value judgments is exhausted by these logical, ethical and aesthetic values. Religion, whose proper concern is with the sacred, does not represent a separate cultural domain. Correspondingly, the sacred does not represent a specific class of values with universal validity alongside truth, goodness and beauty; it embodies all these values inasmuch as they are all related to a supersensible reality.

Like the philosophers of the Marburg School, Windelband also sees the significance of Kant in his re-establishment of the relationship between science and philosophy. At the same time he criticizes Kant - and this distinguishes him from the Marburg School - for his bias in favour of the mathematically orientated natural sciences. In the face of the triumphant emergence of the historical sciences throughout the nineteenth century he sees this as an anachronism. Therefore his efforts are directed towards bringing out their special structure in contrast to the natural sciences. In his speech as Rector of Strasbourg University he defined his approach: the natural sciences operate with universal, apodeictic judgments. They aim at universal statements, which explains their interest in a reality which always remains constant. Their approach is nomothetic, because their aim is to reveal relationships between laws. The price paid for this method is a tendency to abstraction. The historical sciences mitigate this by means of singular, assertive judgments. They are directed towards the particular, which explains their interest in what reveals itself as a unique, intrinsically determined content of reality. Their approach is idiographic, because what they aim to make visible are concrete configurations. For this reason their procedure depends upon intuitive self-presentation.

The main emphasis of Windelband's publications lay in the sphere of the history of philosophy. He was the author of, among other works, a two-volume *Geschichte der neueren Philosophie (History of Modern Philosophy)* (1878-80) and a *Lehrbuch der Geschichte der Philosophie (Textbook of the History of Philosophy)* (1892), which was continued by Heimsoeth and is still reprinted regularly today. In Windelband's view, the history of philosophy has a threefold task. It should:

1 Establish precisely what can be ascertained concerning the living conditions, the intellectual development and the doctrines of the individual philosophers from the existing sources;
2 Reconstruct from this information the genetic process in such a way that in the case of each philosopher it is possible to understand the relationship of his teachings to those of his predecessor, to the general ideas current at the time, to his individual character, culture and education;
3 To judge from an observation of the whole what value can be ascribed to the teachings which have been discovered and whose origins have been explained in the light of the history of philosophy in its totality.
(Windelband 1902: 13)

7 The Southwest German School: Rickert and Lask

As far as Rickert's philosophical development is concerned, his main interest originally lay in questions related to the theory of knowledge and methodology. In his habilitation essay, *Der Gegenstand der Erkenntnis (The Object of Knowledge)* (1921), he criticizes the customary definition of knowledge, which is based on the opposition between real being and a consciousness which groups such being as it is reflected in our representations. He puts forward instead a new concept of knowledge. His starting point for this is a reflection on the primary aim of knowledge, namely the striving after truth. Truth, for Rickert as for Aristotle, lies not in representation but in judgment. However, even if we have to relinquish the concept of a world that is independent of our representations, if judgment as the locus of truth is to be ascribed a central role in the process of knowledge, this approach will allow us to demonstrate a world that is independent of the judging subject, because every judgment is based on the recognition of an 'ought'. Although this 'ought' represents a transcendental order as far as knowledge is concerned, it is not a matter of the order of a transcendent reality, for what we are able to discover is no more than the correct order belonging to the content of awareness, that is to say 'the relationships of representations to each other, which ought to exist and which must therefore be affirmed'.

In his scientific methodology Rickert does not distinguish as Windelband does between nomothetic and idiographic methods, but rather between generalizing and individualizing concept formation. Even if all terms are general inasmuch as they bind general elements together to form conceptual unities, these unities are of a universal nature in the sphere of the sciences, but individual in the sphere of history. For Rickert, the formation of such individual conceptual unities can be explained by their relationship to universal values. This permits a selection to be made from the immeasurable variety of individual given facts within the world of experience. However, the historian's value-orientated procedure should not be understood as representing a subjective valuation of historical events. It is not the historian's job to pronounce on the worth or lack of worth of a particular event such as the French Revolution, but rather to enquire as to the significance of such an event for the history of Europe as a whole. Admittedly, that such historical concept-formation is not arbitrary naturally presupposes the existence of certain generally recognized cultural values. This conclusion, which Rickert recognized was hardly self-evident in his own period, was none the less essential for his argument. His methodological reflections thus culminate in an objective doctrine of value which claims that values enjoy the ontological mode of 'validity' as distinct from the ontological mode of 'existence'.

In his middle period, Rickert drafted a *System der Philosophie (Philosophical System)*, which, however, remained a fragment. In it he conceives of philosophy as articulating a worldview intended to illuminate the meaning of life for us. This, however, involves actually bringing to consciousness the values which make life meaningful. Rickert therefore projects a system of values which he conceives of as an open system. His goal is not 'a complete grasp and enumeration of all valid values', but merely 'a complete formal classification of various types of value' (Oakes 1990: 134). Specifically, this means that he distinguishes between a sphere of contemplative, non-social and substantive values on the one side and a sphere of active, social and personal values on the other.

The attempt to engage with ontological questions is characteristic of Rickert's later phase of thought, yet this need not be interpreted as a break with his original theoretical approach to the problem of transcendental constitution. Indeed, it could be seen as an attempt to pursue this line of thought more deeply. Relevant to Rickert's later philosophy are his *Thesen zum System der Philosophie (Theses on the Philosophical System)* (1932). Here he made it clear that the task of the individual sciences is to comprehend the world of the senses 'either in a universalizing manner (as nature, in so far as it is governed by a system of laws) or in an individualizing manner (as the history of "culture")' (Rickert 1932: 99). On the other hand, he sees a system of values as necessary in order to articulate the intelligible world, because 'meaning and significance can only be properly and rigorously explained by recourse to concepts of value' (1932: 99). Admittedly this 'dualist idea of the world' (*Weltdualismus*) immediately prompts the question of whether there might be an encompassing unity which could bind the two worlds of being and value together. Rickert recognizes this unity of reality and value primarily in the sphere of the non-objectifiable being of human subjects and distinguishes therefore, in addition to the world of experience of sensible and intelligible subjects, a third 'pro-physical' type of worldly being. Of course, the question of the unity of the world is not adequately resolved by this concept. It is impossible to avoid the question concerning a 'transcendent' unity of the world in which value and reality are even more closely connected than in the pro-physical sphere. While in the latter value and reality are only connected through the free acts of the subjects, and otherwise remain separate from one another, here the problem concerns the possibility of an original unity of reality and value in the

supersensuous ground of the world. Rickert leaves us in no doubt that this metaphysical transcendence can only be grasped with the aid of symbolic thought, which interprets material taken from this world as a simile or an image for the beyond.

Lask wrote his doctoral thesis under Rickert on *Fichtes Idealismus und die Geschichte (Fichte's Idealism and History)* (1923-4) and then completed his postdoctoral teaching qualification under Windelband with a study of the philosophy of law. This is an important work for the philosophical system of the Southwest German School because in it Lask understood law as an independent sphere of validity and developed at the same time a methodology of the science of law. However, questions of theoretical philosophy stand at the centre of Lask's philosophical works. For him, everything that can be conceived is divided between the categories of existence and validity. Correspondingly it is necessary to distinguish between knowledge of being and knowledge of validity. Form bears validity, while material being, on the other hand, is utterly foreign to form and therefore does not enjoy the status of validity. The sphere of the sensuously given is then revealed as a realm which lacks this status. For what is sensuously given cannot be deduced by means of logical processes, but can only be acknowledged in its factuality.

It is a characteristic of Lask's understanding of the doctrine of form and material being that a particular form of validity no longer bears a direct relationship to the material, but rather corresponds to a specific material to which it clings (as it were). For Lask, therefore, material being functions as an element which determines meaning. By virtue of this theory of the differentiation of meaning, an independence is attributed to the material of knowledge which stands in direct opposition to the classical Neo-Kantian concept of knowledge, according to which the entirety of the given is determined by the forms of cognition. Correspondingly, at the centre of Lask's conception of the subject we find, not the constitutive activity of the subject with respect to objects, but rather the subject given over to the object. For the relationship of form to the material, which the subject is required to comprehend, precedes all subjectivity. Lask's objectivistic tendency can also be clearly seen in the fact that for him validity is in the first instance free of a relationship to the subject. This relationship only arises when validity is experienced by the subject as an 'ought'. Inasmuch as the subject experiences validity in the shape of a demand, then the conflict of values also comes into play. This occurs because the activity demanded of the subject as regards the recognition of the 'ought' can either succeed or fail. If it succeeds, then the truth attained through this activity appears as a positive value; if it fails, as a negative value. The actual relationship to the validity-content occurs as the judging act which connects subject and predicate and simultaneously contains the affirmation and denial of this connection. It is now important for Lask that the truth lies outside the judgment in the configuration of matter and form. The judgment can correspond to this structure or contradict it. Therefore we can only speak of the judgment's appropriateness to truth or untruth, but not of its truth or falsity as such.

During the final phase of his philosophical development Lask abandons such pure objectivism. Knowledge as a subjective act is once again seen as an independent problem-area of philosophy, although Lask was not prepared to take back any part of his claim concerning the significance of the objectively true with regard to the process of knowing.

8 The Southwest German School: Cohn and Bauch

Cohn's turn towards dialectics is important for his philosophical development. Cohn defines as 'dialectical' all knowledge which 'uses the appearance, the resolution and the reappearance of contradiction as a means of acquiring knowledge'. In contrast to Hegel, Cohn supports a 'critical' dialectic in that he does not presuppose the dogma of the complete transparency of the world to reason. His dialectic is only a 'thinking towards the absolute', but not the kind of thought which could expound the absolute speculatively.

This conception of thought is also evident in Cohn's treatment of the problem of reality. First he distinguishes between three 'forms of reality': (1) the immediate experience of reality, which in his view is the beginning and the point of departure for all other conceptions of reality and thus also the basis for the process of objectivization, (2) the so-called existing factual reality, which represents a first stage in the process of objectivization, because here 'the non-sensational aspects of immediate experience' are excluded, and finally (3) physical reality, which as the final stage of the process of objectivization embodies a 'reality of maximum objectivity' (Flach and Holzhey 1980: 59). But what about the unity of reality in the face of these diverging conceptions of reality? According to Cohn, although this unity is the ultimate aim of human knowledge, it remains unrealizable. It therefore remains an

idea in the Kantian sense: it retains the character of a task which is as essential to knowledge as it is unachievable. Thus Cohn's posthumously published work, which is focused upon the implications of the theory of knowledge for the concrete sciences, is entitled *Wirklichkeit als Aufgabe (Reality as Task)* (1955).

Cohn is not merely interested in questions of theoretical philosophy, as is shown by his major investigation, *Voraussetzungen und Ziele des Erkennens (Presuppositions and Goals of Knowledge)* (1908). Because in general he understands philosophy as a discipline concerned with questions of value, in addition to the realm of logical value he also investigates the realm of aesthetic values; his *Allgemeine Ästhetik (General Aesthetics)* (1901) presents the 'only major work on aesthetics in the Southwest German School' (Holzhey 1992: 45). Questions concerning the systematization of values are the subject of a major work entitled *Wertwissenschaft (Science of Values)* (1932), in which he rejects the thought of a closed value system and interprets the relationship of values to each other in terms of a '*teleological completion*' (*teleologische Ergänzung*).

In connection with the problem of values, Cohn also turned his attention to the philosophy of culture, and on the eve of the First World War he published a paper entitled *Der Sinn der gegenwärtigen Kultur (The Meaning of Contemporary Culture)* (1914). This takes as a starting point the theory that while culture does indeed arise from aspects of human behaviour based on values, it is not created by man's conscious purposive behaviour, because the individual always already finds himself in a specific configuration of cultural life, 'from which he draws substantial content and value' (Cohn 1923: 14), and which he can, of course, seek to transform. With regard to the development of culture in general this produces the following schema: all culture is in the first instance 'bound', that is to say the individual lives totally within the forms which he takes over as being both necessary and self-evident. His consciousness is directed towards interpreting, maintaining and actualizing these forms. In this process his intelligence is strengthened and comes to regard the status quo critically. This means that human beings are presented with new possibilities for shaping their environment, albeit at the price of spiritual homelessness. Against this background, Cohn interprets the present as a time in which the liberated spirit strives to find a new form of fulfilment in life after recognizing this homelessness.

For Cohn, the practical discipline corresponding to the philosophy of culture is pedagogy or theory of education. For this reason he also attempted to establish a philosophical basis for this discipline and saw his treatise *Der Geist der Erziehung (The Spirit of Education)* (1919) as supplementing his study on the meaning of contemporary culture. In his view, the central task of education is the conscious 'development and perpetuation of culture' (*Fortbildung der Kultur*). Education must both encourage the autonomy of the pupil and at the same time ensure their membership of a historical cultural community. This dialectic of liberation and integration is essential to the process of education.

Cohn's importance lies in his development of the initial theories of the Southwest German Neo-Kantianism in the direction of a critical dialectics. Bauch, on the other hand, can be considered as the synthesizer of Southwest German Neo-Kantianism. His major monograph on Kant set out to understand the individual problems of Kant interpretation from the standpoint of the 'Kantian spirit in its entirety'. His systematic works all have a similar aim, suggested by the title of his main philosophical work *Wahrheit, Wert und Wirklichkeit (Truth, Value and Reality)* (1923): he tries to combine various approaches to problems which are generally tackled separately.

On the problem of knowledge, Bauch claims that we must assume a correlation between knowledge of the object and the object of knowledge. Knowledge and object do not simply coincide, but neither can they be completely separated from each other. However, this presupposes that they are both subject to the same conditions. Bauch finds these shared conditions in truth. He analyses individually the structural forms of truth in judgment, category and concept. In the case of judgment he distinguishes between the actual judgment as a 'connection of representations' (*Beziehung der Vorstellungen*), and the logical judgment as an 'objective relationship of validity' (*objektive Geltungsrelation*). The factual judgment can succeed or fail, in other words it is either valid or invalid. It is only valid when it connects up with the validity relation given in the logical judgment. For this, however, it is necessary that it subordinate itself to the latter's validity or, in Bauch's words, that it 'recognizes it'. On the category, Bauch agrees with Kant that 'the category determines the judgment… because the judgment is inseparable in its logical significance from the function of unity which the category represents'. Since the category only makes possible a one-sided determination of the object, if we are to arrive at a complete determination then we must appeal to the concept which, in contrast to the category, refers to the object as concretely given in

intuitive isolation. However, the concept may not be considered in isolation, but must be seen as part of a network of concepts. Bauch names this network ‘idea’.

From the concept of ‘idea’ Bauch makes the transition to the concept of the ‘world’, which for him is nothing more than the appearance of the idea. In this context the concept of system also becomes comprehensible together with the concept of the world. If the idea can be thought of as a system of mutually conditioning concepts, then the world can be seen as a ‘system or relation of conditional things’. In the final analysis, the world cannot be conceived of without an ‘I’, a subject which conceives of the world as having arisen from the idea.

In his practical philosophy Bauch assumes that we encounter the ethical principle *qua* value principle in three forms: (1) as a demand on the will which addresses itself to the will of every rational creature, (2) as a demand for action in the light of the fact that there are certain duties which are only meaningful if specific possibilities of acting exist (consider the Hippocratic oath taken by doctors) and (3) as an essential demand, by which he means the obligation of the individual person to realize their specific essential being. Depending on whether the values as tasks and demands apply to the community as a whole or to individual members of the community, Bauch distinguishes between communal and personal values, which can no more be thought of isolated from one another than can the terms ‘personality’ or ‘community’. On the totality of values, Bauch leaves us in no doubt that values form an ‘interconnected sphere’ and do not exist alone in isolation from each other. Of course this interconnection does not entail enclosure and rigidity. Just as in the development process of knowledge new categories can be created, so the discovery of new values cannot be excluded.

9 The significance of Neo-Kantianism

Neo-Kantianism has often been dismissed as sterile academic philosophy, but this fails to do justice to its real significance. Despite the one-sidedness of its approach, the Neo-Kantian attitude to Kant profoundly influenced the twentieth-century study of Kant’s works. From the perspective of systematic philosophy, the significance of Neo-Kantianism lies first in its development of the concept of ‘validity’ and second in its projected philosophy of culture.

On the first point, the essence of Neo-Kantian thought lies in the strict division it makes between the realm of objects to be grounded and the principles of validity which essentially perform this grounding. According to Neo-Kantianism these principles must show themselves to possess an entirely different character.

If we understand what is principally grounded as the ‘world’, then the transcendental subject which grounds it principally is ‘extramundane’. The consequence of this conception is that all empirical features of the subject must be ascribed to the principal grounded domain, and further that all ontology which regards being as an immediate object of access in itself must be declared obsolete. It was essential to question the radical feasability of the development and transformation of Neo-Kantianism in terms of both the subject and ontology. In the long term, therefore, the issues of the subject and of an ontological presupposition of any kind were equally impossible to ignore.

The significance of the second contribution of Neo-Kantianism, the projected philosophy of culture, lies first in its attempted philosophical reflection on the existence and nature of science. The Marburg School placed its emphasis here on the so-called exact sciences, while the Southwest German School concentrated more on the so-called human sciences. It would be a mistake, however, to reduce the Neo-Kantian philosophy of culture to a specific kind of philosophical theory of value, for Neo-Kantianism devoted itself also to questions of practical philosophy, philosophy of art and philosophy of religion. It is disputed just how far Neo-Kantianism succeeded in its philosophy of culture in gaining a perspective on the political and social reality of its time. It is unquestionable, however, that Neo-Kantianism attempted to advance in this direction, as can clearly be seen, for example, in Cohen’s concept of an ethical socialism, Natorp’s pedagogy, Cassirer’s engagement with the myths of the twentieth century and Cohn’s philosophy of culture. Aside from the question of whether these attempts succeeded, however, it cannot be ignored that the school of Neo-Kantianism also included representatives of a regressive and nostalgic conservatism, such as Bruno Bauch, who in their later works openly defended a populist-naturalist position.

Despite the undeniable limitations of the Neo-Kantian systematic approach and the historical distance between Neo-Kantian and contemporary thinkers, the concern and themes of the Neo-Kantian philosophers have lost none

of their relevance. For now, as then, the issue at stake is the defence of the autonomy of the subject. Since this was seen to be in danger, the Neo-Kantians of both the Marburg and the Southwest German schools insisted on the generative moment inherent in the scientific and cultural form of objectivization, or on an evaluative element which necessarily comes into play with such objectivization. If philosophy today does not wish to capitulate to the current trend towards the repudiation of the subject, then it must follow the strategy already preached by the Neo-Kantians, namely to return to Kantian insights and develop Kant's thought further in a systematic manner.

Neo-Kantianism, Russian

A rather amorphous movement, Russian Neo-Kantianism, in the first decades of the twentieth century, found its most visible and enduring representatives in A. Vvedenskii and his student/disciple I. Lapshin, both of St Petersburg University, who together took a distinct stance within the movement as a whole. Both were chiefly concerned with epistemological issues although their respective publications revealed a much wider field of interests. Both maintained an allegiance to the spirit of Kantian philosophy while devoting little attention to the intricacies of the three Kantian Critiques. In addition, at Moscow University G. Chelpanov adhered to the ideality of the Kantian categories although he upheld an ultimate realism. In the social sciences P. Novgorodtsev and B. Kistiakovskii defended positions revealing a significant debt to the Baden School of German Neo-Kantianism, and as such they were deeply involved in methodological investigations. Several others (N. Berdiaev, P. Struve, G. Shpet) within Russia also briefly espoused a Neo-Kantianism after abandoning Marxism and before moving on to a usually more idealistic stance. Still another, younger group a decade later, centred chiefly around the journal Logos, maintained an idiosyncratic, though not fully articulated, amalgam of Kantian and Hegelian doctrines. The Bolshevik Revolution led to a decimation of what remained of the movement within Russia and a dispersal of its members, who became increasingly isolated from current philosophical trends and issues.

1 Overview of the movement

Russian Neo-Kantianism was neither a unified nor a fully self-conscious movement. Largely as the result of being sent to Germany for further graduate study many young Russian-born scholars returned to their homeland imbued with the dominant trend of their host institution. Like their German counterparts (see Neo-Kantianism) the Russians themselves often shared little more than a conviction that genuine philosophy must begin, though not necessarily end, with Kant. Also similarly to their German counterparts, the Russian Neo-Kantians were not above quarrelling. Yet with their attention fixed on the scene abroad, particularly in Germany, and with their individual, narrow concerns they usually ignored one another, never developing anything similar to the trenchant mutual critiques we find in the competing German Neo-Kantian schools. Although several Russians showed an impulse to systematization, none, with the possible exception of their last representative (Veideman), ever produced a unified work systematically addressing all major philosophical issues. Nor did the Russian Neo-Kantians pen methodic commentaries on any of the three Kantian ’Critiques’ despite one notable excursus into Kant-philology by their leading representative. Partly because they were few in number, but probably more importantly because of the sheer political difficulty of establishing a periodical during the Tsarist era, the Neo-Kantians in Russia had no journal of their own, let alone one for each separate group as in Germany. Even the Russian edition of *Logos*, which was securely in the hands of a young generation of Neo-Kantians, proclaimed itself open to all philosophical directions. The events of 1917 did much to hasten the demise of Neo-Kantianism, although by then its younger members were rapidly moving towards a neo-Hegelian stance.

2 Epistemological Neo-Kantianism

Some scholars trace the beginnings of Russian Neo-Kantianism as far back as the early writings of Pётr Lavrov in the 1860s and Vladimir Lesevich in the 1870s. Nevertheless the first explicit stirrings date from the following decade. Although, unlike the Germans, the Russian Neo-Kantians in general paid little attention to the natural sciences, the initiator, leader and philosophically most influential member of the movement Aleksandr Vvedenskii (1856-1925) started his career with a lengthy master’s thesis - he never attained a doctorate - on the concept of matter. In it he upheld the basic thrust of Kant’s dynamic model of elementary physical processes against the backdrop of contemporary theories. In his mature years he came to call his own stance ’logicism’, which he conceived as a logical proof of the impossibility of metaphysical knowledge and, not immodestly, as the distinctive Russian contribution to philosophy on a par with British empiricism, French positivism and German Kantianism in their opposition to such knowledge. Logicism, in Vvedenskii’s eyes, presupposed no theory of a priori judgment or conclusions about the nature of space and time. Yet he believed it possible to demonstrate, without the elaborate reasoning and considerations found in Kant’s *Critique of Pure Reason* (see Kant, I. §§4-8), that the objects studied by the natural sciences are mere representations of ’true being’, the thing-in-itself, which as such remains totally transcendent.

As all metaphysical hypotheses are irrefutable some can be incorporated into a worldview, though purely on the basis of faith. There is, however, another group of ’views’ that consists neither of metaphysical hypotheses, since the views make no reference to transcendent objects, nor of knowledge claims, since they concern activity in the immanent world. This group is that of our moral tenets. We must integrate into our worldview only those metaphysical hypotheses that are demanded by our moral tenets, only those that we must hold to be true if we are to believe in the ’absolute obligatory nature of moral duty’. Among these hypotheses, or postulates of practical reason, are those discussed by Kant (see Kant, I. §§9-11), but in addition there is one he largely failed to elaborate, namely the existence of mental activity similar to my own in the other.

The Cartesian thesis of the privacy of the mental, that there are no objective criteria by which I know that the other has thoughts and feelings like mine, is one Vvedenskii continued to defend throughout his long professional career at St Petersburg University. The argument from analogy can be of use only in explaining how I extend my conviction in the existence of the other’s mental activity to a number of others but not how I come to my initial recognition (see Other minds). Just as we speak of a moral sense in referring to the recognition of moral obligation, so too can we speak of a metaphysical sense in referring to my acknowledgement of the other’s mental processes. Furthermore, since moral obligation is contingent on the existence of at least one other animate being, I am as certain of the existence of mental activity in the other as I am of the obligatory nature of my duties. In fact, the metaphysical and the moral sense are the same; the former is merely what Vvedenskii called ’the cognitive aspect’ of the latter. In his later years Vvedenskii spoke less of a metaphysical sense and more of accepting the other’s mental activity as a ’working hypothesis’ that proved ’convenient’ in the construction of a scientific psychology.

Not surprisingly, then, Vvedenskii held that psychology as a science yielding knowledge relies necessarily and fundamentally on personal self-observation. Nevertheless he allotted a role, albeit on a secondary level, in a properly conceived psychology to experiment and what he termed ’collective or comparative self-observation’, the accumulation and comparison of introspective observational data by a number of individuals.

Despite Vvedenskii’s wish to found a distinct school of thought his only disciple was Ivan Lapshin (1870-1952), who also taught at St Petersburg University prior to his expulsion from the Soviet Union in 1922. Extending Kant’s original transcendentalism, Lapshin held that even formal logic is grounded in an a priori categorical synthesis. Consequently, anyone who rejects Kantian (or, rather, Neo-Kantian) epistemology has no basis for using the laws of logic. As those laws cannot justifiably be applied in contexts beyond possible experience metaphysics lies beyond the pale of science. Such is the purest expression of ’critical idealism’. Disagreeing with Kant, Lapshin maintained that space and time were essentially not pure intuitions but categories of cognition along with causality, substantiality and so on. Intuited parts of space are merely conceptual ’illustrations’ of space. As a category space is intimately involved in all judgments including analytical ones such as the law of non-contradiction.

Like Vvedenskii, Lapshin devoted considerable attention to the problem of ’the other’. He too claimed that my experience of an immediate givenness of another’s intimate self is illusory. For the most part we analogically infer the other’s mental states from observed bodily movements or positions. Even whether all other rational beings think in accordance with the same laws of logic must be answered agnostically. We are forced to turn to faith. Yet faith can be either immanent or transcendent. A transcendent faith in the other’s self, in other words, that the other has mental states exactly as I do and that they are the ’essence’ of the empirical being before me, is both unnecessary and philosophically unjustified, since it treats the other’s self as a thing-in-itself. On the other hand, immanent faith means we have supreme confidence in the empirical reality, the ’objective significance’, of positing mental states within the other’s empirically observed body.

3 Epistemological Neo-Kantianism (cont.)

While not a disciple of Vvedenskii, Georgii Chelpanov (1863-1936), a professor first at Kiev and then at Moscow University, is almost invariably classed as a Neo-Kantian, although even this is not incontestable. As active in psychology as philosophy he upheld Wundt’s programme in experimental psychology (see Wundt, W.) and defended psychophysical parallelism throughout his career. Vvedenskii himself sharply rebuked Chelpanov for his reliance on J.S. Mill’s ideas in an elementary logic textbook. Yet Chelpanov, unlike many others, sought to retain a role for the thing-in-itself, viewing it as a transcendent something that ’evokes’, along with the forms of

consciousness, a particular representation of an object. Likewise, something analogous to our representation of space ’evokes’ in us that representation. Explicitly in opposition to those who evaded the issue of how to account for a particular representation and called such a position ’transcendental idealism’, Chelpanov termed his stance ‘critical realism’ or ‘ideal-realism’.

While uninterested in the problem of other minds Chelpanov sought to defend the Kantian apriority of space in the light of non-Euclidean geometry by arguing that our particular spatial relations and therefore a particular set of geometrical axioms are formed under the influence of experience. Nevertheless as idealizations the axioms of Euclidean geometry are produced in and by consciousness. Another set of spatial relations will produce another set of axioms. The concept of space simpliciter, however, is a priori in the sense that it is a condition of perception in general. Every space is characterized by its exteriority, and the particular dimensionality of a space is derived from the establishing of a relation between points.

We should also mention Chaim Flekser (pseudonym Akim Volynskii) (1863-1926), a prominent literary critic and editor for a time of the important journal *Severnyi vestnik*. Despite his support for an idiosyncratic, but undeveloped, mysticism Volynskii in an early and lengthy article in that journal held that Kant had conclusively resolved the problems concerning cognition. Kant’s practical philosophy, on the other hand, being based on a ’practical faith’, he held to be imbued with the purest dogmatism.

4 Neo-Kantianism in the social sciences

Pavel Novgorodtsev (1866-1924) took an active role in politics in addition to his duties as professor of jurisprudence at Moscow University. He came under the influence of the Baden and Marburg schools (see Neo-Kantianism §§3-8) during a lengthy stay in Western Europe, particularly in Freiburg. Although endorsing Kant’s epistemology Novgorodtsev’s interests lay mainly in practical philosophy. Whereas Kant’s morality is centred around the notion of duty (see Kantian ethics), Novgorodtsev sought to reconstruct it around that of the unique, harmonious person understood as the sole norm. He seeks to retain the rigour of Kant’s ethical doctrine while recognizing the force of Hegel’s criticism of its formalism by allowing, especially in his early writings, for natural law with a changing content. All practical actions are necessarily limited and incomplete and must be evaluated with their finitude in mind. Nevertheless, laws themselves must be framed keeping in mind the moral foundation of law, the indisputable authority of moral consciousness. In his later writings as the First World War approached Novgorodtsev retreated from his Neo-Kantian programme to a somewhat more traditional conception of natural law.

Bogdan Kistiakovskii (1868-1920) studied for a time under Simmel in Berlin and completed his doctoral studies under Windelband in Strasbourg. After returning to Russia he taught at several institutions including for a short time Moscow University. Kistiakovskii termed his stance, basically a defence of Windelband’s, ’scientifico-philosophical idealism’. He held that just as the basic category in the natural sciences is natural necessity, so in the various disciplines of ’scientific philosophy’ it is found in a consciousness of what should be. Broadly speaking, logic determines what is valuable in a cognitive relation, whereas ethics is concerned with the valuable in practical activity. The normative character of logic is Kant’s greatest discovery in the *Critique of Pure Reason*. Epistemology is concerned not with the very existence of scientific knowledge as a given fact but with the means by which humanity obtains such truths, and with the justification of science.

Nevertheless, Kistiakovskii’s chief interest was not logic but philosophy of the social sciences, where he stood close to the position of Rickert and Weber in Germany. For the social sciences to be legitimate, separate branches of inquiry we must understand how concepts are formed in them. Kistiakovskii denied that categories applicable in the natural sciences can be immediately applied in the social sciences unaltered. Absolute necessity, for example, in the natural sciences is something sought, whereas in the social sciences the search for necessity is but one viewpoint.

Also among those influenced by the Baden school was the historian Aleksandr Lappo-Danilevskii (1863-1919), who taught at St Petersburg University. Although chiefly noted for his concrete historical studies he accorded a singular role to epistemology in the elaboration of principles and methods without which scientific advancement is inconceivable. While sharing the Baden view that the natural sciences are nomothetic and the social sciences primarily but not exclusively idiographic, he also saw a difference in their goal. The natural scientist sought to

explain nature whereas the social scientist strives for understanding of a phenomenon.

The most partisan Russian disciple of the Marburg School, particularly in the philosophy of the social sciences, was Vasilii Savalskii (1873-1915). In his chief work from 1908 he engaged in polemics against Kistiakovskii and Novgorodtsev while expounding the position of Hermann Cohen in ethics and jurisprudence.

5 Transitional Neo-Kantians

Several notable Russian intellectuals early in their respective careers abandoned Marxism and briefly adopted a Neo-Kantian position before moving on to another, usually more idealistic philosophy. Perhaps best known among these was Nikolai Berdiaev (1874-1948). Although acknowledging the primacy of practical reason in one of his earliest publications from 1900, he nevertheless saw this as a psychological truth. Berdiaev held Kant's atemporal postulates of practical reason to be 'temporary postulates of people of a specific socio-psychological formation'. At a different time other interests could predominate leading to a different set of postulates. However, Berdiaev came to the view that there were unalterable moral values which, while atemporal, were in the course of history expounded by different classes. Along these lines he attempted to combine Kantian idealism with a lingering sympathy for Marxian sociology.

Pëtr Struve (1870-1944), a dynamic personality in Russian politics as well as intellectual history, came to Neo-Kantianism largely out of dissatisfaction with the account of freedom and necessity in Marxian philosophy of history. During his Neo-Kantian phase he retained a belief in the validity of a thorough-going determinism for the phenomenal realm while asserting that freedom, conceived as indeterminism, was a 'reality' in the activity of the human individual.

In his first published article from 1907 on Hume and Kant, Gustav Shpet (1879-1937) sided with the Baden-school outlook that while the validity of the law of causality was undemonstrable, we must believe in it for the sake of cognition. Within a few years, however, he abandoned Neo-Kantianism altogether, drawing close to Husserlian phenomenology.

6 The journal *Logos*

A Russian edition of the international journal *Logos* began in 1910 under the responsible editorship of Sergei Hessen (1887-1950) and Fëdor Stepun (1884-1965). In 1911 Boris Iakovenko (1884-1948) was added. Hessen studied in Heidelberg and Freiburg with among others Windelband and Rickert, under whom he wrote a notable dissertation. After returning to Russia he taught in St Petersburg and Tomsk. Subsequently after the Bolshevik Revolution he taught in Prague and Warsaw. Although later in emigration he wrote on pedagogy and philosophy of law his early writings reveal a strong debt to the Baden School. He argued that in the natural sciences to subsume a particular natural event under a general law, thereby illuminating it in a causal sequence, is to understand it. The individual or historical event too is marked with necessity even though the degree of generality appears markedly different in historical and scientific explanations. To understand an event in history is to understand it in its concreteness, its individuality but also its necessity no less than in the natural sciences.

Stepun studied in Heidelberg under Windelband under whom he wrote a slim dissertation on Solov'ëv. Shortly after the Revolution he briefly served as cultural director at a state theatre in Moscow. Later he taught sociology at Dresden University and from 1946 in Munich. His early affiliation with Neo-Kantianism consists chiefly in his view that philosophy must examine all cultural fields, distinguishing in them a 'transcendental-formal element' from that which is merely contingent. This formal element is a manifestation of the absolute and as such is what gives cultural 'creations' their universality and necessity. Unfortunately Stepun failed to develop these thoughts more precisely or fully.

After 1917 Iakovenko first lived in Italy and then Berlin and Prague. Despite his many writings he devoted little attention to enunciating his own position either in detail or rigorously. In short he held to an absolute monism but proclaimed transcendental philosophy to be the intellectual path to the Absolute. In it philosophy has attained a self-consciousness. The next and last step for philosophy is to return to the original unity revealed in mythology. When philosophy has come full circle it will then be critical and rational.

7 The last Russian Neo-Kantians

Vasilii Sezeman (1884-1963) was born in Finland and studied in St Petersburg. After graduation from the university there he went abroad to Marburg and Berlin for further study. Returning to Russia he taught during the First World War in Petrograd and later in Saratov. In the early 1920s he lived briefly in Berlin and then in Lithuania, where he taught philosophy at the Universities of Kaunas and Vilnius. During this later period his major writings were composed in German, although a few years prior to his death he published a Lithuanian translation of Aristotle's *De Anima*. Particularly interested in bestowing a transcendental significance on the concept of evolution without falling into psychologism, Sezeman held that knowledge at any particular time is incapable of seizing the transcendent object. Absolute knowledge remains the ideal, but it itself is inseparable from the path leading to the latter. Each stage in the advance of knowledge functions as a constitutive element in this ideal. As truth is a regulative idea there are no absolute, self-evident truths; all propositions are subject to evolution including the categories or seemingly ultimate elements of knowledge. Sezeman thus rejects interpreting the thing-in-itself as some causative transcendent reality and views it instead as an ideal, self-contained system.

Aleksandr Veideman (1879-?) published in Latvia in 1927 the only attempt at a systematization in Russian Neo-Kantianism which nevertheless stands as the 'swan song' of the movement. Situating himself between Kant and Hegel, Veideman faulted the former for limiting himself to the possibility of mathematical and scientific knowledge, not knowledge in general. Had Kant done so he would have affirmed that all being is created by thought dialectically. As thought here is conceived to be a logical not individual process, solipsism is averted. The impetus for creative cognition receives its answer in ethical striving. Aesthetics represents the field wherein the finite is raised to an ideal.

As in the parallel German movement concern with the historical Kant was greatest during the early years of the respective protagonists and gradually diminished. In some cases this was simply a matter of an evolving thought-process, whereas in others external events surely played a decisive role. Vvedenskii distanced himself from the intricacies of Kant's 'First Critique', seeking an independent and 'easier proof of philosophical Criticism'. Chelpanov, witnessing the consolidation of Marxism in Russia in the 1920s, sought above all to defend moderation and the toleration of competing viewpoints in philosophy. To this end he emphasized his own hostility and that of Marx to transcendent metaphysical explanation. Lapshin, increasingly isolated in Prague, turned ever more towards studies of Russian culture. As the years turned into decades Sezeman, perhaps alone among the Neo-Kantians in the Russian diaspora, continued working without thematic abatement on problems traditionally conceived as philosophical, keeping abreast of the latest developments.

THOMAS NEMETH

List of works

Berdiaev, N. (1900) 'F.A. Lange i kriticheskaia filosofiia' ('F.A. Lange and Critical Philosophy'), in *Mir bozhii* (1900) July: 224-54.(Reveals a side to his thought far different from his later 'existentialist' turn.)

Chelpanov, G. (1896-1904) *Problema vospriiatiia prostranstva v sviazi s ucheniem ob apriornosti i vrozhdënnosti (The Problem of the Perception of Space in Connection with Theories of Apriority and Innateness)*, Kiev: Kushnerov, 2 vols.(Of his numerous works his most scholarly.)

Chelpanov, G. (1905) *Vvedenie v filosofiiu (Introduction to Philosophy)*, 6th edn, Moscow: V.V. Dumnov, 1916. (Admirably clear and simple prose.)

Hessen, S. (1909) *Individuelle Kausalität. Studien zum transzendentalen Empirismus (Individual Causality. Studies in Transcendental Empiricism)*, Berlin: Reuther & Reichard.(A treatment of an issue central to the Baden School of Neo-Kantianism.)

Kistiakovskii, B. (1899) *Gesellschaft und Einzelwesen. Eine methodologische Untersuchung (Society and the Individual. A Methodological Investigation)*, Berlin: Verlag Otto Liebmann.(A Neo-Kantian examination of the foundations of sociology that paralleled much of Weber's methodological work.)

Kistiakovskii, B. (1916) *Sotsial'nye nauki i pravo (Social Sciences and the Law)*, Moscow.(A general theory of law from the standpoint of sociology.)

Lappo-Danilevskii, A. (1910-13) *Metodologiia istorii (The Methodology of History)*, St Petersburg, 2 vols.(A monumental study by a distinguished historian.)

Lapshin, I. (1906) *Zakony myshleniia i formy poznaniia (Laws of Thinking and Forms of Cognition)*, St Petersburg.(Despite its frequent departure from academic style this is his basic work.)

Lapshin, I. (1924) 'Oproverzhenie solipsizma' ('A Refutation of Solipsism'), repr. in *Filosofskie nauki* (1992) 3: 18-45.(A valiant though vain attempt to overcome the limitations of his own essentially methodological

solipsistic stance.)

Novgorodtsev, P. (1901) *Kant i Gegel' v ikh ucheniiakh o prave i gosudarstve (Kant and Hegel on Law and the State)*, Moscow: Moscow University.(Far more than simply an examination of Kant and Hegel.)

Novgorodtsev, P. (1909) *Krizis sovremennogo pravosoznaniia (The Crisis of Contemporary Legal Consciousness)*, Moscow: Moscow University.(The major statement of his fully developed position.)

Savalskii, V. (1908) *Osnovy filosofii prava v nauchnom idealizme (Foundations of the Philosophy of Law in Scientific Idealism)*, Moscow: Moscow University.(Highly polemical.)

Sezeman, V. (1911) 'Ratsional'noe i irratsional'noe v sisteme filosofii' ('The Rational and the Irrational in a Philosophical System'), in *Logos* 2: 93-122.(An early generally mediocre essay.)

Shpet, G. (1907) *Problema prichinnosti u Iuma i Kanta, (The Problem of Causality in Hume and Kant)*, Kiev: St Vladimir University. (Unfortunately Shpet states his own position only at the very end.)

Veideman, A. (1927) *Myshlenie i bytie (Thinking and Being)*, Riga.(An almost unknown, albeit sketchy, amalgam of Neo-Kantianism with elements of Hegelianism.)

Volynskii, A. (1889) 'Kriticheskie i dogmaticheskie ėlementy v filosofii Kanta' ('Critical and Dogmatic Elements in Kant's Philosophy'), in *Severnyi vestnik*, (1889) 7: 67-87; 9: 61-83; 10: 89-109; 11: 51-72; 12: 55-78. (Surprising support for Kant from an unexpected corner.)

Vvedenskii, A. (1901) *Filosofskie ocherki (Philosophical Essays)*, 2nd edn, Prague, 1924.(Contains a number of valuable pieces illuminating his general philosophical outlook.)

Vvedenskii, A. (1909) *Logika, kak chast' teorii poznaniia (Logic as a Part of a Theory of Cognition)*, 3rd edn, St Petersburg: Stasjulevich, 1917. (His basic text on epistemology.)

Neoplatonism

Neoplatonism was the final flowering of ancient Greek thought, from the third to the sixth or seventh century AD*. Building on eight centuries of unbroken philosophical debate, it addressed questions such as: What is the true self? What is consciousness and how does it relate to reality? Can intuition be reconciled with reason? What are the first causes of reality? How did the universe come into being? How can an efficient cause retain its identity and yet be distributed among its effects? Why does the soul become embodied? What is the good life?*

There were several flavours of Neoplatonism, reflecting the concerns and backgrounds of its practitioners, who ranged from Plotinus and his circle of freelance thinkers to the heads of the university schools of the Roman Empire, Proclus, Ammonius and Damascius. In the later, more analysed form, we see a rich scheme of multi-layered metaphysics, epistemology and ethics, but also literary theory, mathematics, physics and other subjects, all integrated in one curriculum. Neoplatonism was not just a philosophy but the higher education system of its age.

The Neoplatonism that came to dominate the ancient world from the fourth century was an inseparable mixture of inspired thought and scholastic order. To this may be traced some of its internal conceptual conflicts: for example, the free individual soul versus the ranks of being, personal experience versus demonstrative knowledge. To this may also be traced its appeal to polar audiences: mystics and mathematizing scientists, romantics and rationalists.

To the Neoplatonist, knowledge consists of degrees of completion. Take the example of tutor and student. Both study the same things, but the tutor has a wider and more intimate knowledge. The tutor opens the student's mind to the breadth and intricacies of the study-matter, and corrects the student's deliberations. So it is with the Neoplatonic levels of knowledge. Every level has access to the entire spectrum of what there is to know, but each with its appropriate adverbial modifier. At the 'lower' level an individual comprehends things 'particularly' and is concerned with the 'images' or presentations of mind and sense-impressions of the qualities of physical things. At the 'higher' level, an individual apprehends things 'wholly', as universal statements (often called 'laws' and 'canons'). The concern is with propositions about what is true or false, self-grounded and logically necessary. Thus the higher level corrects and supplies the 'criterion' for the lower level.

Knowledge, however, is not an end in itself, but a means to salvation. Increasing awareness puts us in touch with the levels of reality of which we ourselves are part. The ultimate reality is none other than the fundamental unity out of which all came into being: God. In this union we recover our true good.

As the summation of ancient Greek philosophy, Neoplatonism was transmitted to Byzantium, Islam and western Europe. It was the prime intellectual force behind the protagonists of the Italian Renaissance, and its influence was felt until the nineteenth century.

1 Who, what, when?

The modern label 'Neoplatonism' conveniently describes the philosophy of late antiquity, and at once misrepresents it. It was neither 'new', a departure from Plato, nor simply a 'Platonism' (see Plato; Platonism, Early and Middle). The more we learn of the philosophers from the first century BC to the second century AD, such as Cicero, the Middle Platonists and Neo-Pythagoreans, the more we discern a continuous line of thought (see Cicero; Neo-Pythagoreanism). How far back it stretches is still intriguing and controversial, since several leading scholars have indicated independently a proximity in thought between Neoplatonism and the late Plato and his immediate successors in the Old Academy (see Speusippus; Xenocrates). The Neoplatonists were known in their time as 'Platonists'; those at Athens regarded themselves the true successors to Plato, and called their school the 'Academy'. But these ancient labels mislead as much as the modern, and to understand the sources of Neoplatonism we have to look also to the Stoics and the commentators on Aristotle (see Stoicism; Aristotle Commentators). Plato's and Aristotle's schools disappeared as institutions in the first century BC. Freelance philosophers took up the different causes. In the second century AD the Roman emperor-philosopher Marcus Aurelius (§1) established chairs of philosophy at Athens (apparently bearing the title 'successor') in Platonism, Aristotelianism, Stoicism and Epicureanism. Alexander of Aphrodisias, in his endeavour to unify the Aristotelian corpus, identified the active intellect (*nous*) with god and with its intelligible object, unintentionally easing the

absorption of Aristotle in mild Platonism. By the beginning of the third century imperial funding for the chairs had vanished, and by the end of that century only Platonists survived. Some, who were more inclined to scholasticism, flourished at the prestigious teaching centres of the late Roman Empire, Athens and Alexandria. Others, particularly those of the Neo-Pythagorean tendency, such as Numenius, flourished at other centres, notably Apamea (Syria). Both sorts took up relevant ideas from past Greek philosophies, including Aristotelian theories of logic and mind, and rejected those they considered fruitless (Epicureanism) or wrong (for example, the dualism of the Platonist Plutarch of Chaeronea §3).

This is the philosophy that Plotinus, Porphyry and Iamblichus turned into a fresh, highly integrated school of thought, now called, for lack of a better term, Neoplatonism. Each of the three founders contributed something different, often in reaction to their teacher. Plotinus abandoned scholastics in favour of a Pythagorizing Platonist, Ammonius Saccas, at Alexandria. Later, he set up his own circle of followers in Rome, which was to prove highly influential. Porphyry first studied under the leading scholastic at Athens (Longinus) but then studied under Plotinus. Only five years later he abandoned Plotinus and pursued his explicit 'harmonization' of Aristotle with Plato. Iamblichus taught philosophy at Apamea. He had read Porphyry and may have been his student, but disagreed with him over the approach to the divine. One of Iamblichus' disciples, Aedesius, founded a celebrated school at Pergamum, and proselytized the emperor Julian. By the fifth century the Iamblichean version had spread to the main teaching establishments at Athens (see Damascius; Proclus; Simplicius) and Alexandria (see Ammonius, son of Hermeas; Philoponus), as well as Gaza (which was Christian).

Neoplatonists saw their metaphysics in all forms of expression, provided they could find the appropriate level of interpretation. Language is the mediator of concepts and realities, and so even literary works (for example, those by Homer and Hesiod) allude to metaphysical truths. Similarly, revelatory proverbs, the Orphics and the Chaldaean Oracles, point to truths that transcend ordinary description (see Orphism; Chaldaean Oracles). The Neoplatonists did not admit irrationalism, however, remaining within the Greek rationalist manner of explanation.

Their writings are mostly commentaries on classical greats, Plato and Aristotle - although there are notable exceptions, including the *Enneads* of Plotinus, Porphyry's *On Abstinence from Animal Food*, Iamblichus' *On the Mysteries*, Proclus' treatises *On Providence, On Fate*, *On Evil* and *Platonic Theology* and Damascius' treatise *Problems and Solutions on First Principles*. As a textual form, the commentary is no evidence of lack of originality: it was the conventional form of scholarly writing of the middle and late imperial period, and was useful for teaching. Good interpretative works contained critical appraisals and innovative theories using the set text as a frame for the commentator's own reflections. That two Athenian heads of school (Proclus and Damascius) wrote most of the commentaries on Plato, while the Alexandrians concentrated on Aristotle, was not due to an ideological split, but to avoidance of duplication. The Alexandrian professors were envious of the rich endowments given to the Athenians and the Athenians looked with disdain on the money-making compromises of the Alexandrians, but the two schools enjoyed close bonds, and students from the one regularly travelled to take positions at the other (for example, Hierocles, Hermeias, Ammonius, Damascius and Simplicius).

On the Latin side, Plotinus' and Porphyry's works were translated by the pagan Macrobius and the Christian convert Marius Victorinus. The latter transformed Neoplatonism to a form suited to Roman Christianity and influenced Augustine and Boethius (see Marius Victorinus; Augustine; Boethius, A.M.S.).

On the Greek side, Neoplatonists supported Hellenism as a civilizing culture and as a universal, pagan religion, at a time of Christian emperors. The school at Athens ended with the emperor Justinian's imperial ban on pagan public teaching in 529. There was an unsuccessful sojourn to Persia, but it is still a mystery what finally happened to the last Athenian scholarchs, Damascius, and especially Simplicius, who flourished after the ban. At Alexandria, Neoplatonic teaching continued with the pagan Olympiodorus, and then with Christians (Elias and David). In the seventh century, Alexandrian teaching transferred to the Byzantine capital, when Stephanus was invited to teach at the university of Constantinople (see Byzantine philosophy §§2,3).

2 The curriculum of knowledge and virtue

The Neoplatonic curriculum was established by Iamblichus, and maintained with minor changes by Athenians and Alexandrians over three centuries until the end of independent Neoplatonist schools (whence it was transmitted to Byzantium). It consisted of thematic topics tuned to educational 'scopes'. Beginning with Aristotle's logic (first

through Porphyry’s *Introduction*) and practical ethics, it progressed to physics, the mathematical sciences, Aristotle’s metaphysics, and twelve of Plato’s dialogues culminating with the *Timaeus* and *Parmenides*. After approximately six years of university education, the student graduated as a philosopher and a virtuous person.

From Socrates and Aristotle, Neoplatonists accepted that *aretē* (virtue) can be taught (see Aretē): however, this is not to say that teachers impart goodness to students, but that they make the students fully aware of their true nature. Each grade of the curriculum was meant to stimulate the appropriate virtue. According to the Platonic *Alcibiades I*, *psychē* (soul/life/mind) is the human essence (see Psychē). Educating the person means educating the soul as to its true origins and place in the scheme of things. Thus, education and ethics are grounded in epistemology and metaphysics. Concentrating on the essence of things involves a certain detachment from incidentals, the temporal, physical events. The soul must be ’unaffected’ (*apathēs*) by externals. Eventually a sense of completion and full awareness bring about the state of wellbeing (*eudaimonia*) that is the goal of human life (Eudaimonia). Ultimately this is nothing else than ’becoming similar to God’.

As there are many degrees of awareness, so there are many levels of virtue. The physical (*physikai*) virtues relate to a well-maintained body: for example, genetic characteristics, beauty, state of health, stamina. Ethical (*ēthikai*) virtues relate to the sense of justice, courage, temperance and truth (the four Platonic cardinal virtues) and, generally to the temperament of the individual, including, it seems, the quality of memory. Social (*politikai*) virtues measure regard for one’s fellow human beings, participation in politics and affairs at large: for example, standing up for human welfare and dignity against state officialdom (compare Aristotle’s definition of the human being as social animal). The three types outlined above belong to the ’lower’ level because they refer to passing matters, not to the atemporal essence of life. The first of the ’higher’ virtues are the purifying (*kathartikai*) virtues. The detachment of the soul can be assisted through a simple lifestyle consisting of abstinence and vegetarianism (Porphyry was the first to write on its philosophy), fasting and praying. Erotic love was not shunned, and most of the Neoplatonist scholarchs enjoyed fertile marriages. The aim was to redirect desire towards the eternal. Next are the intellectual (*theōrētikai*) virtues: learning about names (*onomata*) as signifying concepts (*noēmata*) of real objects (*pragmata*), both natural and divine. Iamblichus added also a sixth type, the theurgic virtue. What exactly he meant is still controversial, but it included initiation in magic, prediction of natural disasters, out-of-body visions and, in general, acting like god while being a mortal. The leap to the transcendent absolute was theurgy’s highest aim. Finally, there was the ‘paradigmatic’ virtue, which in earlier Neoplatonism denoted the exemplary state of divine union but in later Neoplatonism was reserved solely for divine beings.

3 Epistemology, metaphysics and the daring soul

Pure sense-perception ranks low in the scale of certainty, because its information is incidental and transient. Mind arrives at an opinion or judgment (*doxa*) by assimilating sense-impressions into images (*phantasiai*) and comparing them with preconceived patterns of thought, which are intelligible and can be articulated, thus forming the mind’s internal objects. Certain, scientific knowledge (*epistēmē*) is the result of reasoning. This is the mental discourse (*dianoia*) in which mind weighs concepts, some abstracted from physical properties, others found inherent in formal relations (for example, mathematics) or in the method of pure reasoning. Above discursive reasoning Neoplatonists placed ’intellection’ (*noēsis*), which is contemplation. They saw it as pure thinking (*nous*) in the sense of grasping unmediated truths as a ’simultaneous whole’. For Plotinus this meant that the knower identifies with what is to be known. Others asserted that the two coincide (Proclus, *Platonic Theology* I, ch. 21, 97.22-98.5) so that we can still articulate propositions: perfect identity comes at a higher level. Grasping the ultimate truth, which has no differentiation, entails a complete unity, an ’illumination’. Plotinus described it as mental rapture, but Iamblichean Neoplatonists deduced that it is fully supra-intellectual, brought about by ’faith’ (*pistis*).

We assimilate knowledge with our *psychē* (soul, or the personal mind). It is what makes us alive and thinking. Not localized in a part of body or anywhere in the cosmos, it is as individual as the body it animates. *Psychē* exercises diverse activities, non-rational, vital, intellectual and spiritual. It can combine divine, intellectual inspiration and sensory perceptions into one mental object. Plotinus made *psychē* very flexible. The rest kept it between intellect and body, and sometimes distinguished its non-rational ’nature’ (*physis*).

Education, knowledge, science, ethics and psychology are thus grounded in metaphysics: the kind of existence that substantiates them. Degrees of learning, awareness or ’consciousness’ and virtue, reflect degrees of being.

Humans, plants, gods and every existent thing are made up of a ’bundle’ of the appropriate layers of being. In the basic scheme these are: physicality, soul, intellect, the One. Intellect (*nous*) is the objective, self-absorbed intelligence that creates by imposing ’form’. On a universal scale it is the Creator. The unqualified One is the supreme principle of all that exists in some sense: that is, the ultimate God. In itself it is beyond the system, transcending determination. Later Neoplatonists distinguished aspects within soul and intelligence. In this way, they arrived at a richer scheme: pure body, physicality, rational soul, intellect, life-principle (process), substantive essence (object-pattern) and the One. They also distinguished class properties as ’wholes’ and ’parts’. For example, the complete soul is an unanalysed whole, but its ’parts’ are the souls resident in individual living beings. This distinction helped specify ’unity’ (*henas*) as the ’root’ of the characteristic identity of a being, whether universal or particular. In later Neoplatonism (notably in Proclus) this is the spark of divinity.

The grades of being can be imagined as spheres of increasing comprehensiveness. Bodily existence is perfected by soul, this by the objective intellect, and so on. The One embraces everything. Conversely, there is a cascade of causation, from the One to the ’many’. Neoplatonists were still faced with problems: How can diversity emerge from undifferentiated unity? Why should a perfect state give rise to others? In response they proposed that such causation is not voluntary but a necessary consequence of perfection, which has no external limits (so divine action is not a mystery, unlike in the revealed religions). Existence ’unfolds’. This dispersion is like a light ’emanating’ from its source and diffusing into space, or as a ’procession’ of numbers from one to two, three, four…. Things (and levels) lose their foremost identity by gaining separate existence. They preserve the character that determines them by an act of ’returning’. However, Neoplatonists were not satisfied with the One being both the original cause of intelligible reality and transcending it, and to the end argued over solutions (as indeed cosmologists and theologians do to this day).

The problem also appeared at the level of soul. Why does *psychē* leave its own proper level of being and ’descend’ to a mortal body? Ontology requires an organizing principle to preserve the ever-disintegrating body. But something complete in itself cannot want something like the material body. Soul’s self-consciousness gives a sense of ’dare’ (*tolma*) that enables its departure and blind fall. Later Neoplatonists pointed out that perfect souls (for example, the moving and organizing principle of the cosmos) do not suffer such a fate. The ’particular’ souls are not completely aware what they are, and so leave their own order: either to ’fall’ to body, or to ’ascend’ towards the One. In this way the daring soul acquires a wide but personal experience.

4 Philosophy of science

The Neoplatonists taught the mathematical quadrivium of arithmetic, geometry, astronomy and harmonics, and the physics of Aristotle and Plato: Plato’s *Timaeus* belonged to the highest section of the curriculum. In the sixth century we also see Galen’s medicine appearing at the Alexandrian school, and we have a certain Stephanus of Athens writing as a philosopher-physician.

The programme of mathematization can be traced to Iamblichus’ reform (with the influence of Neo-Pythagoreans), although Pythagorizing mathematics is found in Plato himself. Part of the enterprise was the mathematization of physics and matter. Proclus and Simplicius declared that ’quantity’ is more fundamental than ’quality’. Iamblichus and later Neoplatonists were excited about mathematics because mathematical knowledge alone proceeds by the ’solidity of scientific demonstration’ (Elias, *On Porphyry’s Introduction* 28.24-9). Religious speculation and the physicist’s empiricism do not, and therefore need mathematics to support them. Mathematics thus became a pillar of Neoplatonic metaphysics and epistemology. Proclus pointed out that mathematical proofs rely on indemonstrable axioms, and so philosophy has to turn to a higher science - Platonic dialectic.

In ancient philosophy the concept of time related to change, movement and the psychological experience of events. Place was associated with the container where change happens and so with theories of matter. Neoplatonists stayed true to the Platonic outline, that time is the ’moving image of eternity’, but in fleshing it out they arrived at startling conclusions. For Plotinus, time is the product of psychological movement. It is the life of the soul as it moves from one activity to another ‘restlessly’. Since soul is not confined to individuals but is what gives life and movement to the universe, there is a cosmic time. By this account, eternity is the timelessness ’of that quiet life…which belongs to that which exists and is in being, all together and full, completely without extension or interval’ (*Enneads* III.7.3). The later Neoplatonists rejected Plotinus and followed Iamblichus in giving time its own reality. In this way they finally broke with Greek tradition. The time of ordinary experience is not true time

but the ’flowing’ appearance of it. Even the cosmic clocks, the stars and planets and the revolution of the universe as a whole, do not reveal what time is. Like the ’centre of a rotating wheel’ (Proclus, *Commentary on Plato’s Timaeus* 3.27), primary time is singular and motionless, and abides before creation. Damascius took Neoplatonic innovation further by proposing that ordinary time flows not by atomic instants but as a series of ’strides’ or ’leaps’ (each of which is a temporal part).

Neoplatonists rejected Aristotle’s view of place as a boundary. In developing instead Plato’s ‘receptacle’ of creation, they arrived at the full identification of place with three-dimensional space (see Space). Proclus equated space with massless body, and contemplated universal space as the absolute frame of cosmic motion. Others saw space as incorporeal. For the Christian Neoplatonist Philoponus, pure space is more fundamental than matter, and is a void. Iamblichus elevated place to the realm of Forms, and made space the instrument by which the world-soul binds things in their proper positions. For Damascius place really was the power that keeps the members of the universe in their arrangement. Simplicius returned to space as extension, and distinguished relative from absolute space, the latter being indistinguishable from essence. In examining the relationship of ’when’ and ’where’, he concluded that the two are ’siblings’, thereby anticipating the modern equal ranking of time and space.

5 Influence

Neoplatonists were influential through their philosophy, through their preservation of ancient Greek thought (for example, Simplicius is one of our two major sources for the Presocratics), and in their capacity as the educators of late antiquity. Their curriculum passed to the Byzantines, and a Latin fifth-century Neoplatonist, Martianus Capella, devised an influential allegory on the seven liberal arts. Indeed, it is hard to find thinkers of the early medieval period who were not influenced by Neoplatonism. In eleventh-century Byzantium, still find scholars arguing for (Psellus) or against ancient Neoplatonists, and so to the end in the fifteenth century (Plethon).

Theologians found it appealing that rational argument can sustain religion and a life of selfless goodness. However, several philosophical conclusions - for example, that God the transcendent is distinct from the Creator, involuntary divine action, the perpetuity of the physical world, the unimportance of accidental events (incarnation) - conflicted with religions based on the Bible. Moreover, the Neoplatonists tended to defend the Hellenic religion: Porphyry wrote an extensive scholarly refutation of Christianity. As a result Neoplatonist influence often went uncredited. A striking example of this was, the late fifth century theologian who wrote under the name ’Dionysius the Areopagite’ (see Pseudo-Dionysius). He produced an entire Christian theology, ’hierarchy’, by adapting the Athenian multi-layered system. Between the seventh and ninth centuries this was taken up by leading theologians of the Greek East and the Latin West. It is even claimed that a prototypical Gothic cathedral, St Denis, was built on Pseudo-Dionysian/Neoplatonic principles. Another example was a collection of works attributed to Aristotle but compiled from Plotinus and Proclus. They first occur in Arabic. Later they were translated into Latin. Both the Pseudo-Dionysian and pseudo-Aristotelian corpora were correctly identified by Aquinas.

Muslims came into contact with Neoplatonism with their first conquests of Syria and Egypt (seventh century). In the next three centuries they translated and paraphrased most of the Greek texts they found. With the Muslim expansion into Spain, the Arabic books became a source of Greek ideas for western Europeans. Some Neoplatonic texts still survive only in Arabic. Neoplatonism influenced Islamic philosophy and religion (Ismailism) (see Ibn Sina; Neoplatonism in Islamic philosophy).

Jewish thinkers had already participated in Platonism with Philo of Alexandria. Much later, living in the Muslim dominion, the eleventh century thinkers Gabirol (see Ibn Gabirol) and Gersonides developed Plotinian themes on intelligible matter and the active intellect. In the twelfth century, Neoplatonism was influencing the emerging Kabbalah in the south of France (see Kabbalah). Next we find it in Renaissance Kabbalism (see Bruno, G.; Pico della Mirandola, G.), and finally in the famous Dutch Jew, Spinoza.

Western Europe first inherited Plotinian-Porphyrian Neoplatonism through Augustine and Boethius, and later received Byzantine Neoplatonism. They influenced both mystics and logicians, for example, Duns Scotus, Anselm of Canterbury, Abelard, Eriugena, Albert the Great, Grosseteste and Thomas Aquinas. The Renaissance marked the recovery of Greek texts in the original, and a new wave of influence began (see Platonism, Renaissance). Proclus had been recognized since Aquinas’ time; now Plotinus (and Plato) became finally known. The Byzantine Neoplatonist Plethon was invited by the Medici to set up the Platonic Academy of Florence, where Ficino and Pico

della Mirandola taught. Their impact extended to European art, literature and landscape theory. The Hellenic rationalism of Neoplatonism appealed to the Humanists, particularly the idea that individuals possess their own means for salvation. This was also the message of Christian mystics such as Eckehart: even theologians such as Nicholas of Cusa upheld it. The late Neoplatonists' love for mathematics appealed to scientists who disliked medieval explanations by qualities. In art, the Neoplatonic light metaphysics and theories on mathematics and representation proved fruitful in the invention of perspective.

When Plato was separated from Platonists, (Neo)platonic influence declined. Notable exceptions were the Cambridge Platonists (see Cambridge Platonism) and the Idealists - both the British (see Berkeley, G.; Bradley, F.H.) and, especially, the Continental (see Bergson, H.-L.; Schelling, F.W.J. von; Hegel, G.W.F.). In science, Schelling and Hegel contributed to *Naturphilosophie*, which saw the forces of nature (magnetism, electricity, gravity) as the unfolding of one unified force (see Naturphilosophie). In literature, the English Romantics (Blake, Shelley) were influenced through Thomas Taylor. Coleridge was interested both in *Naturphilosophie* and, preoccupied with the origin of inspiration, in Schelling's investigations into the 'unconscious'.

Neoplatonism in Islamic philosophy

Islamic Neoplatonism developed in a milieu already saturated with the thought of Plotinus and Aristotle. The former studied in Alexandria, and the Alexandrine philosophical syllabus included such figures as Porphyry of Tyre and Proclus. Associated with these scholars were two major channels of Islamic Neoplatonism, the so-called Theology of Aristotle and the Liber de Causis (Book of Causes). Other cities beloved of the philosophers at the time of the rise of Islam in the first century AH *(seventh century* AD*) included Gondeshapur and Harran.*

Islamic Neoplatonism stressed one aspect of the Qur'anic God, the transcendent, and ignored another, the creative. For the Neoplatonists, all things emanated from the deity. Islamic philosophers were imbued to a greater or lesser degree with either Aristotelianism or Neoplatonism or, as was often the case, with both. Al-Kindi, the father of Islamic philosophy, has a Neoplatonic aspect, but the doctrine reaches its intellectual fruition in the complex emanationist hierarchies developed by al-Farabi and Ibn Sina. Their views are later developed (or metamorphosed) by later thinkers into an emanative hierarchy of lights, as with Shihab al-Din al-Suhrawardi, or the doctrine of the Unity of Being espoused by Ibn al-'Arabi. While al-Ghazali and Ibn Rushd both vigorously opposed Neoplatonic views, the latter attacked the former for his general opposition to the philosophers.

Neoplatonism itself had a major impact on that sectarian grouping of Muslims known as the Isma'ilis, and became the substratum for its theology. Historically, Neoplatonism in Islam achieved its climax with the Fatimid Isma'ili conquest of Egypt towards the end of the fourth century AH *(tenth century* AD*). While Neoplatonism later declined in philosophical importance in the face of rampant Aristotelianism and Hanbalism, it may be said to have bequeathed an important religious, historical and cultural legacy to the Islamic world, which in the Isma'ili movement endures to this day.*

1 Milieu and sources

Islamic Neoplatonism developed in a milieu which was familiar with the doctrines and teachings of Plotinus. The city of Alexandria, into which the Arab armies of Islam marched in AD 642, had down the centuries been home to many philosophies and philosophers: Plotinus himself, the founding father of Neoplatonism, studied in Alexandria for eleven years under the scholar Ammonius Hierocles. The Alexandrian philosophical syllabus was imbued with Neoplatonism and coated with Aristotelianism. The works of important Neoplatonists such as Porphyry and Proclus were studied there. Two works, whose exact authorship is unclear but which became associated with Porphyry and Proclus respectively, were the famous *Theology of Aristotle* and the work which became Latinized as the *Liber de causis* (see Liber de causis). Both these works, regardless of their actual authorship, were major channels of Islamic Neoplatonism. The *Theology of Aristotle*, despite its name, had nothing to do with Aristotle but summarized, with some additions, Books IV-VI of Plotinus' *Enneads*. The *Liber de causis (Book of Causes)* had its basis in the *Elements of Theology* by Proclus. The Neoplatonic themes in both the *Theologia* and the *Liber* are not difficult to identify, ranging from the key doctrine of emanation through references to the hypostases such as the Universal Intellect and Universal Soul (*Theology of Aristotle*) or the Procline hypostases of the One, Existence, Intellect and Soul (*Liber de causis*), to the sublime attributes of the One (see Neoplatonism).

However, Alexandria was not the only major city in the Middle East to foster the rise of Neoplatonism before the rise of Islam. Another was Gondeshapur, a great centre of Greek Byzantine learning, especially in the fields of philosophy and medicine, where Aramaic rather than Persian appears to have been the dominant language. This city, built by Shapur I in the mid-third century AD, acted as a magnet to many Middle Eastern intellectuals in both the pre-Islamic and Islamic periods. The great father of the Arabic translation movement, Hunayn ibn Ishaq, studied there; earlier, Nestorian scholars had fled to that city after the Council of Ephesus in AD 431. These scholars knew the work of Aristotle, but they had also studied Porphyry and so were familiar with the teachings of Neoplatonism. The closeness of Gondeshapur to what became Baghdad meant that the former city was able to infiltrate the latter, when it became an Islamic seat, with a variety of Greek elements.

Then there was Harran in northern Syria, a city which was home to the star-loving Sabaeans, a pagan sect whose transcendent theology was imbued with Neoplatonic elements. In the third century AH (ninth century AD) Harran was visited by refugee scholars from the schools of Alexandria; in the following century these scholars moved from Harran to Baghdad, bringing to that last city elements, both Aristotelian and Neoplatonic, from the rich

philosophical heritage of both Alexandria and Harran. Of course, cities such as Alexandria, Gondeshapur and Harran were not the only sources of Neoplatonic thought, but their examples serve to illustrate the ease with which the expanding Arab-Islamic Empire came into contact with Greek thought, especially in its Aristotelian and Neoplatonic incarnations. And it was between the latter that the pendulum of Islamic philosophy frequently swung in the writings of the individual Islamic philosophers, when they were not actually mixing the two in a glorious intellectual syncretism as happened with the thought of the Ikhwan al-Safa' (see Ikhwan al-Safa').

2 The God of Islamic Neoplatonism

The description of God in the Qur'an is by and large fairly clear, though it did give rise to complexities of interpretation in Islamic theology centring on such matters as anthropomorphism, God's omnipotence and man's free will, and the attributes of God. The Qur'anic God, however, is both transcendent and immanent. There is none like him but he is also closer to man than man's jugular vein. He intervenes in human history to reveal himself to man, for example in the revelations of the Qur'an, and sends angels to fight for his prophet Muhammad, as at the Battle of Badr in AD 624. Here he is often like the God beloved of today's process theologians (see Process theism). Above all, however, the Qur'anic God is one who creates *ex nihilo*. There is no concept of Neoplatonic emanation in the Qur'an. In contrast, for Aristotle, God is the Unmoved First Mover. The emphasis in Aristotelian theology is much more on God's movement rather than on his creation, which is limited in any case to his production of form in prime matter which has existed eternally. With the Neoplatonists, the emphasis moves from the concept of creation to that of eternal emanation: God or the One or the Good - however he is to be characterized - does not create *ex nihilo* but 'engages' in eternal emanation of all that is below him.

Thus in the Middle East at the time of the rise and spread of Islam there were at least three different 'theologies' vying for space, emphasising different qualities of their deity. There is the Qur'anic God as creator *ex nihilo*; there is the Aristotelian God as first Mover; and there is the Neoplatonic God as eternal emanator. The debate which was engendered about the relationship between God and the rest of observable and intangible reality and phenomena became a fundamental characteristic of the writings of the Islamic philosophers. The Qur'anic God was linked to his creation by the sheer power of creativity, the Aristotelian God was linked - much less feelingly - with that which moved, while the Neoplatonic God bridged, or attempted to bridge, the huge gulf between transcendence and corporeal reality by the device of emanation. A brief survey of the thought of some individual Islamic philosophers will serve to illustrate how the debate featured in their writings, and thus in the general development of Islamic philosophy.

Abu Yusuf ibn Ishaq al-Kindi is universally acknowledged by scholars of Islamic philosophy as the 'Father of Islamic Philosophy'. Al-Kindi's God has four faces or aspects. Doctrinally, he is classically rooted in and derived from the Qur'an, and bears such epithets as 'creator' and 'active'. God has an essential unity which does not derive from anything else. He also has Aristotelian aspects - he is, for example, unmoved - but of course al-Kindi's deity is much more than a mere Mover. God's attributes are also discussed by al-Kindi in Mu'tazilite terms and al-Kindi espouses a Mu'tazilite antipathy towards anthropomorphism (see Ash'ariyya and Mu'tazila §4). Finally, we can detect a Neoplatonic influence on al-Kindi's thought. He was the first major Islamic philosopher to reflect significant aspects of the Neoplatonic tradition, and is a bridge to the thought of philosophers such as al-Farabi and Ibn Sina.

It is with these latter two philosophers that Islamic Neoplatonism reaches its apotheosis, where such fundamental Neoplatonic concepts as hierarchy and emanation are fully developed and integrated into a metaphysics of being. Al-Farabi is rightly regarded as the father and founder of Islamic Neoplatonism, while Ibn Sina, though less original, is often considered to be Islam's greatest Neoplatonic philosopher. While the deity that he portrays certainly has other aspects, it is the Neoplatonic aspects which draw our attention. Like al-Farabi, Ibn Sina has a complex scheme of emanation with ten intellects emanating from the Necessary Being. Again as with al-Farabi, emanation constitutes a bridge between the unknowable God of Neoplatonism and earthbound humanity. However, the theological terminology deployed in Ibn Sina's thought is perhaps less negative than that of al-Farabi; this is particularly true of the mystical dimension of Ibn Sina's thinking.

Neoplatonism in Islam may be said to have reached its furthest limits of development in the thought of Isma'ili theologians such as Hamid al-Din al-Kirmani on the one hand, and that of Shihab al-Din Yahya al-Suhrawardi and Muhyi al-Din Ibn al-'Arabi on the other. Al-Kirmani espouses a Farabian elaboration of God and ten intellects in

his Neoplatonic emanationist hierarchy. Al-Suhrawardi, 'the Master of Illumination' (*shaykh al-ishraq*), as he became known, established an extraordinary complex Neoplatonic hierarchy of lights in which the divine and quasi-divine are seen all in terms of light. God is the Light of Lights (*nur al-anwar*), and from him emanates the First Light from which emanates the Second Light and so on; but bound into the whole system is a complex three-tier system of Angelic Lights. Because of the doctrine of emanation, the lights (or intellects) have an ontological or noetic precedence, the one over the other, but not a temporal precedence. By contrast, Ibn al-'Arabi employs Neoplatonic terminology to bolster his doctrine of the Unity of Being (*wahdat al-wujud*). The circularity of his thought, however, precludes the elaboration of a classical system of emanation following Plotinian, or even Farabian, lines. It may be argued that the terms 'theophanies' or 'manifestations' (*tajalliyat*) of the divinity, rather than 'emanations', are a more accurate rendering of his thought.

3 Reaction and counter-reaction

The reaction and counter-reaction to the infiltration of Neoplatonism into Islamic thought and philosophy may usefully be studied in the writings of the great Abu Hamid al-Ghazali, Sunni theologian and mystic, on the one hand and those of Islam's most notable Aristotelian, Abu'l Walid Muhammad ibn Rushd, also known as Averroes, on the other. In his *Tahafut al-falasifa (Incoherence of the Philosophers)*, al-Ghazali (§3) attacked both the Neoplatonists and Aristotle. He rebutted, for example, the idea that the world was eternal, and tried to show mathematically that the thesis of the Neoplatonists was illogical. He believed that the Neoplatonists had failed to prove that God was One, and attacked their beliefs about a variety of other fundamental and crucial points such as divine knowledge and the question of the immutability of God. The two principal philosophers whose views al-Ghazali attacked were al-Farabi and Ibn Sina. As al-Ghazali himself put it:

> However, the most faithful - as Aristotle's translators - and the most original - as his commentators - among the philosophizing Muslims are al-Farabi Abu Nasr, and Ibn Sina. Therefore, we will confine our attention to what these two have taken to be the authentic expression of the views of their mis-leaders…. Therefore, let it be known that we propose to concentrate on the refutation of philosophical thought as it emerges from the writings of these two persons.
>
> (Tahafut al-falasifa: 5)

In all, al-Ghazali itemized twenty particular problems 'in whose discussion in this book we will expose the contradiction involved in the philosopher's theories'.

If al-Ghazali represents Islamic theology's most biting attack on philosophy and severest reaction to Neoplatonism in Islam, Ibn Rushd represents the counter-reaction. This is not to say that the latter wholeheartedly espoused the views of the Neoplatonists: indeed, very far from it. In his *Tahafut al-tahafut (Incoherence of the Incoherence)*, referring to the incoherence of al-Ghazali's *Tahafut al-falasifa*, Ibn Rushd wrote a work which Fakhry has described as 'the product of Ibn Rushd's maturest thought [which] constitutes a systematic rebuttal of al-Ghazali's critique of Greco-Arab philosophy' (Fakhry 1983: 276). Al-Ghazali is accused of misunderstanding, and it is clear that Ibn Rushd is concerned to defend the merits of philosophy as a mode of non-heretical thought while at the same time not accepting the theses of the Neoplatonist philosophers. Despite his intention in the *Tahafut al-tahafut* of defending the philosophical targets of al-Ghazali's wrath, Ibn Rushd, as Bello points out, 'more often than not…does not, in fact, defend al-Farabi and Ibn Sina…. Instead, he shows to what extent they have departed from the authentic Aristotelian philosophical doctrines, and sometimes joins his voice with that of Ghazali in convicting them of heresy' (Bello 1989: 15). Thus Ibn Rushd, despite his defence of philosophy and philosophers, is more than happy to declare open war on Neoplatonism.

4 The influence and legacy of Islamic Neoplatonism

While it is certainly untrue to say that Islamic philosophy came to a sudden end with the death of Ibn Rushd, we can say that his death in AH 595/AD 1198 marks the approaching end of the great debates about Neoplatonism in Islamic thought. By then the kind of peripateticism espoused by Ibn Rushd may be said to have at least revived, if not definitely triumphed over, other forms of philosophy. The death of Ibn al-'Arabi in AH 638/AD 1240 marks that triumph, for the latter's doctrine of *wahdat al-wujud* was perpetuated by only a few faithful disciples. Furthermore, other movements had arisen in competition with Neoplatonism and Aristotelianism, such as the literalism of the Spanish Muslim Ibn Hazm, and the Hanbalism of Ibn Taymiyya. Neoplatonism as a radical system of

philosophical thought with a controversial theological agenda was enshrined in the writings of such thinkers as the Ikhwan al-Safa’, but generally speaking its greatest surviving influence was, and is, on the theology of the Isma‘ili sect in Islam, one of the three great divisions of Shi‘ism. This sect achieved its political apotheosis with the coming to power of the Fatimid Isma‘ili dynasty in North Africa and Egypt in the fourth and fifth centuries AH (tenth and eleventh centuries AD). The Mosque-University of al-Azhar was a beacon of Isma‘ili (and thus Neoplatonic) thought before the Ayyubids took possession of Egypt and returned it to the Sunni fold. Today, Neoplatonism in Islam survives principally as the philosophical substratum which underpins the theology of the Isma‘ilis, a group which, though itself split over issues of leadership, nonetheless holds many theological and philosophical points in common.

If we examine the impact of Neoplatonism on Islamic thought generally, it is clear that this philosophy served to emphasize that transcendent aspect of God which is to be found clearly in the Qur’an, sometimes at the expense of the immanent. The impact of Neoplatonism on the course of Islamic history itself has been considerable in some regions. Among many examples we may note that the Fatimid dynasty came to power in Egypt and ruled there from AH 297-567 (AD 969-1171); the Isma‘ili Assassins flourished at the Castle of Alamut from AH 483-654 (AD 1090-1256); and a Nizari Isma‘ili imamate later moved from Persia to India. Theologically then, it is clear that a body of doctrines, so many of which seemed at odds with mainstream Islamic teaching, served at times to highlight the Qur’anic emphasis on transcendence and was actually absorbed by one, albeit heterodox, sect to become the foundation for that sect; while historically, Neoplatonism from its mainly theoretical Middle Eastern origins in Alexandria, Harran, Gondeshapur and elsewhere became sufficiently powerful to ‘hijack’ an entire dynasty, the Fatimid.

We may extrapolate from all this, then, the paradigm of an ‘alien’ cult which becomes ‘Middle-Easternized’ and ‘Islamicized’ and which acts on occasion as theological stimulus, irritant, gadfly or foundation, and in so doing ultimately inserts itself from a variety of perspectives into the broad and multivalent fabric of Islam. Alternatively, we may choose to examine the phenomenon of Neoplatonism rather more closely, assess its emphasis on order, structure, emanation, hierarchy, transcendence, intellect and soul, and extrapolate a rather different paradigm, perhaps more akin to that preferred by the Isma‘ilis. According to this view, Neoplatonism would not be regarded as a foreign or invasive growth within the body politic of Islam but rather as something which, despite its emphasis on emanation rather than *creatio ex nihilo* and other real differences from mainstream Islamic theology, addressed an aspect or aspects of Islam which had been neglected or overlaid by other matters in the development of that faith. It is useful perhaps to ponder Lenn and Madeleine Goodman’s observation: ‘Emanation was perfected by the neo-Platonists, quite consciously as an alternative to creation because the learned neo-Platonic philosophers did not choose to redescend into the anthropomorphic cosmogenies from which Aristotle had rescued them with great difficulty only a few centuries earlier’ (Goodman and Goodman 1983: 31).

Neo-Pythagoreanism

Neo-Pythagoreanism is a term used by modern scholars to refer to the revival of Pythagorean philosophy and way of life in the first century BC*. It coincides with the redevelopment of Platonic thought known as Middle Platonism. Neo-Pythagoreans elaborated a mathematical metaphysics in which the highest level of being was occupied by a transcendent principle, equated with 'the One' or 'the Monad' and regarded as the source of all reality. Neo-Pythagorean anthropology reaffirmed the ancient Pythagorean belief in the immortality of the soul. Although Neo-Pythagoreanism is often indistinguishable from Middle Platonism, it is characterized by a tendency to see Pythagoras as the father of all true philosophers, including Plato. In the third century* AD *Neo-Pythagoreanism was absorbed into Neoplatonism.*

As the name implies, Neo-Pythagoreanism is a renewal of Pythagoreanism (see Pythagoreanism). Since the reanimators were philosophers of a Platonic stamp, it is particularly the kind of Pythagoreanism found in Plato and the early Academy that came to be renewed and developed further. Plato incorporated Pythagorean number theory in the *Timaeus* (see Plato §16) to provide a mathematical structure for the universe. In the so-called 'Unwritten Doctrines' he posited two first principles, the One (or Monad) and the Indefinite Dyad, essentially developments of the Pythagorean primal opposites, Limited and Unlimited (see Philolaus §2; Plato §5; Platonism, Early and Middle §2-4; Pythagoreanism §2). The One, identified with the Good, is the determining principle, which acts upon the Dyad (the Two), the passive principle. Their interaction generates numbers that are equated with the Platonic Forms (the Form-numbers), of which the physical world is but a reflection. The One and the Dyad were taken over, with certain modifications, by Plato's immediate successors, Speusippus (§2) and Xenocrates (§2). In the subsequent history of Platonism, until the first century BC, Pythagorean metaphysical speculation went into abeyance, notably during the sceptical phase of the Academy when all forms of dogmatism, which would include the positing of mathematicals as the eternal and invariable archetypes of reality, were rejected (see Academy; Arcesilaus §2).

Although the Hellenistic age marks a fallow time for the serious pursuit of Pythagoreanism, it was a period remarkably productive of Pythagorean texts, known as pseudepigrapha. Their authors either preferred to remain anonymous or purported to be older Pythagoreans. Some of these compositions are religious-didactic, some philosophical but with little original inspiration. None the less, their concern to show that the teachings of Plato and Aristotle were of ancient Pythagorean provenance found great resonance with Neo-Pythagoreans, and several pseudepigrapha were considered authoritative texts.

Pythagorean philosophy resurfaced in earnest in the early first century BC after Antiochus issued his call 'to follow the ancients'. In the course of a renewed interest in the original works of Plato, the *Timaeus* gained particular prominence, a dialogue that now came to be seen virtually as a Pythagorean tract. A notable commentator on the *Timaeus* was Eudorus of Alexandria. His first principles are Monad and Dyad, but above these he posits a supreme One, also called the Supreme God. 'Becoming like God' was the goal of life. While Eudorus is a Platonist, he presents his doctrines as 'Pythagorean' and thus counts as an important witness to the 'Pythagoreanizing' current in Platonism (see Platonism, Early and Middle §§4,8-9).

The first *bona fide* Neo-Pythagorean was Moderatus of Gades. In his *Pythagorean Lectures* he establishes a system of three Ones: a One beyond being, a One in the realm of the Ideas that acts as a divine craftsman (Demiurge) upon the Dyad, bringing matter into existence, and a One that participates in the first two and permeates the world (the World-Soul). Moderatus' triad foreshadows the three *hypostases* - One, Intellect, Soul - of Neoplatonism (§3).

Nicomachus of Gerasa has a similar triad. His first God, the Monad, appears, however, to be identified with the Demiurge, who in combination with the Dyad produces the Logos - or the Forms, equated in accentuated Pythagorean-Platonic fashion with mathematicals (see Logos §1). Much of Nicomachus' philosophy must be extracted from his *Theological Arithmetic*, a work in which he identifies the traditional Hellenic gods with numbers. This number-mysticism excited the interest of later Neoplatonists, especially Iamblichus.

With Numenius of Apamea (Syria) we reach the zenith of Neo-Pythagorean thought. While a Platonist from our

viewpoint, Numenius put Pythagoras, Socrates and Plato on an equal footing and was generally regarded as a Pythagorean in antiquity. He also proclaimed three gods, but in his attempts to separate the Monad, the absolute Good, from all association with creative activity and matter (the Dyad for Numenius is co-eternal with the Monad and embodies an evil principle), his philosophy assumes a starkly dualistic character, reminiscent of ancient Pythagoreanism.

In addition to metaphysics, Neo-Pythagorean philosophers reaffirmed the immortality of the soul and transmigration (see Pythagoreanism §3). There are also indications that, along with the renewal of Pythagorean philosophy, came a revival of the Pythagorean lifestyle with its emphasis on spiritual and bodily purity. This is evidenced especially in Roman Pythagoreanism. Cicero credits one Nigidius Figulus with renewing an extinct Pythagoreanism. Although we know nothing of the speculative thought of Figulus, Cicero's testimony accords well with the general picture of a Pythagorean reawakening in the first century BC, which in the Roman world undoubtedly took a very practical form. In the next century, under the emperor Augustus, a circle of Pythagorean philosophers formed around Quintus Sextius, the 'Sextii', whose ethical precepts had considerable impact on Seneca (§1). The emperor Tiberius employed a Pythagorean court-philosopher named Thrasyllus.

After flourishing in the hands of Numenius, Neo-Pythagoreanism came to an end with the waning of the second century AD. But with Middle Platonism, with which it had always gone hand in hand, it lived on as major force in Neoplatonism. Plotinus, Porphyry, Iamblichus, Proclus, to name just the most famous Neoplatonists, not only wrote on Pythagorean themes (we owe two of our extant biographies of Pythagoras to Porphyry and Iamblichus) but also were indelibly marked by the philosophy that bore the name of Pythagoras.

Neumann, John von (1903-57)

Von Neumann was one of the great mathematical minds of the twentieth century. His work has affected philosophy on several fronts, including logic and the philosophy of science. He also had great influence upon developments in the philosophy of mind: the computer model of mind employed during the middle-to-late twentieth century was explicitly based upon the von Neumann computer architecture. Although late twentieth-century philosophy of mind has largely rejected the von Neumann machine as a model of brain activity, his pioneering work in cellular automata has provided a basis for subsequent development in 'distributed' or 'connectionist' computer architectures.

John von Neumann was described by mathematician Jacob Bronowski as 'the cleverest man I ever knew, without exception. And he was a genius, in the sense that a genius is a man who has *two* great ideas'. But von Neumann was even cleverer than that, doing foundational work in logic and set theory, quantum mechanics, computer design and the theory of computation, and game theory, to mention only those contributions of immediate interest to philosophers. In pure mathematics, von Neumann also produced important work in measure theory and the spectral theory of operators in Hilbert space, as well as introducing the theory of 'rings of operators' (now known as von Neumann algebras). In applied mathematics, he did groundbreaking work in numerical analysis in connection with fluid dynamics, the theory of turbulence and the physics of shock waves.

Born in Budapest, Hungary, von Neumann was educated at the Lutheran *Gymnasium* and was then tutored privately in mathematics when his extraordinary abilities became apparent. Though enrolled at the University of Budapest, von Neumann appeared there only to take exams, instead spending his time in Germany and Switzerland studying physics and chemistry and visiting David Hilbert in Göttingen to discuss mathematics. He took a chemical engineering degree at the Federal Institute of Technology in Zürich in 1925 and a doctorate in mathematics at Budapest in 1926 (his dissertation concerned the axiomatization of set theory). He was named *Privatdozent* at the University of Berlin (1927-9), and then at Hamburg (1929-30). In 1930-1 he became a visiting lecturer at Princeton University in New Jersey, and subsequently professor of mathematics there until he joined the Institute for Advanced Study (also at Princeton) in 1933, becoming its youngest permanent member. During the Second World War, von Neumann participated in various war-related scientific enterprises for the USA, in particular the atomic bomb project at Los Alamos. In 1954 von Neumann was appointed to the USA's Atomic Energy Commission. He died of bone cancer in Washington, DC in 1957.

Among von Neumann's accomplishments in set theory (see Set theory) are his elegant treatment of ordinal numbers (in which each ordinal number is the set of all smaller ordinal numbers), the first rigorous treatment of definition by transfinite induction, and an axiomatization of set theory more technically intricate than that of Ernst Zermelo and Abraham Fraenkel. This axiomatization and its successors have turned out to be useful in mathematical research. With respect to mathematical logic, von Neumann participated in Hilbert's programme in metamathematics, publishing proofs of consistency for parts of arithmetic until Kurt Gödel's 1931 results made such activity moot (see Gödel's theorems).

In quantum theory, von Neumann provided the first rigorous axiomatization of quantum mechanics, contributed to measure theory and proved an ergodic theorem for quantum systems. His *Mathematische Grundlagen der Quantenmechanik (Mathematical Foundations of Quantum Mechanics*, 1932) gives his argument that no introduction of 'hidden parameters' can eliminate the statistical character of statements of quantum theory unless the theory itself is fundamentally changed (see Quantum mechanics, interpretation of).

Von Neumann introduced the theory of games in a 1928 paper, providing a mathematical description of games and strategy and stating and proving the minimax theorem (see Decision and game theory). (Game theory is also known as 'decision theory' because a game in von Neumann's sense includes bluffing and, in selecting a move, taking into account what you think your opponent thinks you are going to do.) His later collaboration with Oskar Morgenstern (1944) extended game theory to mathematical economics.

Computer design and theory of computation are the areas of von Neumann's work which have had the most widespread influence among philosophers. Von Neumann's computer design was influential for two main reasons:

the machine architecture appears ‘brain-like’ at an abstract level (or so many philosophers thought); and the design could be implemented using high-speed components available at the time (resulting in an actual computer which could perform impressive computations).

A von Neumann machine consists of three primary components (a ‘central control unit’, a ‘central arithmetic unit’ and a finite uniform ‘memory’) and input and output ‘organs’. (The analogy with the human body is discussed in von Neumann’s ‘First Draft of a Report on the EDVAC’ (1945).) The central control unit interprets instructions while the central arithmetic unit executes operations on data contained in the memory; a crucial feature of a von Neumann machine is that the instructions are also stored in the uniform memory. Thus the functional status of the contents of any particular memory location is indeterminate: if it is executed, it is an instruction; if it is operated upon, it is data. A von Neumann machine exploits this indeterminacy: the machine can modify its own program during execution. This feature both allows the high-speed implementation of basic programming constructs and explains why the von Neumann architecture was regarded as ‘brain-like’.

Subsequent developments in artificial intelligence and neuroscience, however, have led to the rejection of the von Neumann machine as a model of brain activity. Basic cognitive processes (for example, pattern recognition) are computation-intensive, and neurons are too slow (and too unreliable) to complete them accurately in real time given a von Neumann computer organization. If the brain is a digital computer, it must have a non-von Neumann architecture.

Interestingly, in the 1940s von Neumann was already working on developing a general theory of natural and artificial automata; his particular areas of concern were self-reproducing automata and the synthesis of reliable systems from unreliable components. His early work on McCulloch-Pitts ‘neural networks’ (see McCulloch and Pitts 1943) made von Neumann himself a pioneer in non-von Neumann computer architectures.

List of works

Neumann, J. von (1961-3) *The Collected Works of John von Neumann*, ed. A.H. Taub, Oxford and New York: Pergamon Press, 6 vols.(Organized chronologically by topic, with an exhaustive bibliography. Of particular interest to philosophers: papers on logic, set theory and quantum mechanics in volume 1; computer design and automata theory in volume 5; and game theory in volume 6.)

Neumann, J. von (1986) *Papers of John von Neumann on Computing and Computer Theory*, ed. W. Aspray and A. Burks, The Charles Babbage Institute Reprint Series for the History of Computing, vol. 12, Cambridge, MA: MIT Press.(The best introductory source for von Neumann’s writings on computing; includes relevant papers from the *Collected Works*, including the 1945 and 1946 papers on von Neumann architecture, some papers not in that collection, and the first part of von Neumann (1966), with useful introductions by A. Burks. Includes a bibliography of von Neumann’s publications in all subjects, and a convenient bibliography of computer research contemporary with von Neumann and building on his work.)

Neumann, J. von (1928) ‘Zur Theorie der Gesellschaftsspiele’, *Mathematische Annalen* 100: 295-320; trans. S. Bargmann, ‘On the Theory of Games and Strategy’, in *Contributions to the Theory of Games*, vol. 4, Princeton, NJ: Princeton University Press, 1959, 13-42.(The paper in which von Neumann invented game theory; includes the first statement and proof of the minimax theorem.)

Neumann, J. von (1932) *Mathematische Grundlagen der Quantenmechanik*, Berlin: Springer; trans. R. Beyer, *Mathematical Foundations of Quantum Mechanics*, Princeton, NJ: Princeton University Press, 1955; repr. in the Princeton Landmarks in Mathematics and Physics series, Princeton, NJ: Princeton University Press, 1983. (Von Neumann’s axiomatization of quantum mechanics and his development of a mathematical theory of measurement in quantum mechanics; includes his argument that if the basic structure of quantum theory is to remain unchanged, the statistical nature of statements of the theory cannot be eliminated by the introduction of ‘hidden parameters’.)

Neumann, J. von and Morgenstern, O. (1944) *Theory of Games and Economic Behavior*, Princeton, NJ: Princeton University Press.(The foundational work in mathematical economics. Chapter 1, which explains the basis for the extension of game theory to economics, is accessible to a general audience, but the remainder very quickly becomes technically intricate.)

Neumann, J. von (1945) ‘First Draft of a Report on the EDVAC’ (for the US Army Ordnance

Department/University of Pennsylvania), repr. in *Papers of John von Neumann on Computing and Computer Theory*, ed. W. Aspray and A. Burks, Cambridge, MA: MIT Press, 1986; corrected version, *IEEE Annals of the History of Computing* 15 (4): 27-75, 1993.(This paper specifies the first logical design of an electronic computer whose program could be both stored and modified electronically. It incorporated, without credit, work by J.P. Eckert, Jr and J. Mauchly, which led to a dispute over who really originated the 'von Neumann' architecture. See Goldstine (1972) and especially Williams (1985) for accounts of the controversy. For justification of the corrections in the 1993 version, see Godfrey and Hendry (1993).)

Neumann, J. von, Burks, A. and Goldstine, H. (1946) 'Preliminary Discussion of the Logical Design of an Electronic Computing Instrument' (US Army Ordnance Department/Institute for Advanced Study, Princeton, NJ), repr. in *The Collected Works of John von Neumann*, ed. A.H. Taub, Oxford and New York: Pergamon Press, 1963, vol. 5, 34-79; and in *Papers of John von Neumann on Computing and Computer Theory*, ed. W. Aspray and A. Burks, Cambridge, MA: MIT Press, 1986, 97-142.(This paper completes the description of what became known as the 'von Neumann architecture' by incorporating a random access memory along with the stored program concept articulated in von Neumann (1945).)

Neumann, J. von (1950) *Functional Operators*, vol. 1, *Measures and Integrals* (Annals of Mathematics Studies 21), vol. 2, *The Geometry of Orthogonal Spaces* (Annals of Mathematics Studies 22), Princeton, NJ: Princeton University Press.(Notes compiled from lectures on measure theory given at the Institute for Advanced Study at Princeton in 1934.)

Neumann, J. von (1951) 'The General and Logical Theory of Automata', in L. Jeffress (ed.) *Cerebral Mechanisms in Behavior: The Hixon Symposium*, New York: Wiley, 1-31; repr. in *The Collected Works of John von Neumann*, ed. A.H. Taub, Oxford and New York: Pergamon Press, 1963, vol. 5, 288-328; and in *Papers of John von Neumann on Computing and Computer Theory*, ed. W. Aspray and A. Burks, Cambridge, MA: MIT Press, 1986, 391-431.(A slightly revised version of a paper delivered at the Hixon Symposium (1948) reflecting on the influence of McCulloch and Pitts (1943) on the design of digital computers, and speculating on the direction von Neumann would later take in his work on self-reproducing automata; accessible to a general audience and a nice introduction to his work in this area.)

Neumann, J. von (1958) *The Computer and the Brain*, New Haven, CT: Yale University Press.(The text of the 1956 Mrs Hepsa Ely Silliman memorial lectures, which von Neumann was too ill to deliver at Yale University; accessible to a general audience.)

Neumann, J. von (1960) *Continuous Geometry*, Princeton, NJ: Princeton University Press.(Notes from lectures given at Princeton 1935-7 on a topic von Neumann invented in 1935 by considering geometric interpretations of von Neumann algebras.)

Neumann, J. von (1966) *Theory of Self-Reproducing Automata*, ed. A. Burks, Urbana, IL: University of Illinois Press.(Based on lectures given at the University of Illinois in 1949.)

(1985) *A History of Computing Technology*, Englewood Cliffs, NJ: Prentice-Hall.(A reliable and very accessible introduction to computing devices, with particular attention paid to mechanical details; includes a balanced account of the attribution controversy over the von Neumann architecture.)

Neurath, Otto (1882-1945)

An Austrian socialist philosopher, economist, sociologist and historian, Neurath was a charismatic orator and an energetic cultural activist. Deeply concerned with education as a tool for social progress and cooperation, he founded museums and created the Isotype language for visual education. During the Bavarian Revolution he headed a plan for the centralized socialization of the Bavarian economy. A determined supporter of the scientific attitude and opponent of metaphysics (which he believed to have pernicious political and social consequences), he was a founder member of the Vienna Circle and a heterodox proponent of logical empiricism. He spearheaded the Unity of Science Movement that launched the project of an encyclopedia of unified science.

1 Life

Otto Neurath was born on 10 December 1882, in Vienna, son of Gertrud Kaempfert and Wilhelm Neurath, social reformer and political economist. He received a doctoral degree in Berlin in the history of economics in 1906. A study of the Balkans led to his theory of war economy as a natural (non-monetary) economy upon which he based his programme for full socialization. In 1919 the short-lived Bavarian socialist government appointed him head of the Central Planning Office. From 1920 to 1934 Neurath participated actively in the direction of Viennese socialist politics, especially in housing and adult education. He founded the Social and Economic Museum of Vienna, which created the 'Vienna method' of picture statistics and the Isotype language ('International System of Typographic Picture Education'); the Verein Ernst Mach, which, with the publication of an intellectual manifesto in 1929, became the public face of the Vienna Circle; the International Foundation for Visual Education at the Hague; and the International Unity of Science Movement. The latter, inspired by the ideas of the French Encyclopedists, launched the project of an Encyclopedia for Unified Science. Together with the pictorial languages, this scientific encyclopedia would promote social solidarity and progress at an international level. Neurath fled from the Nazis, first to The Hague, then in 1940 to England, where after nine months of internment he resumed activities related to the Isotype method and the unity of science. He died in Oxford on 22 December 1945.

2 Science and society: empiricism in the social sciences (1910-31)

Neurath championed 'the scientific attitude'. He denied any value to philosophy over and above the pursuit of work on science, within science and for science. His views on the language, method and unification of science were led throughout by his interest in the social life of individuals and their well-being. This concern is reflected in his engagement both in political life and in social science. For Neurath, to theorize about society is inseparable from theorizing for and within society (see Marxist philosophy of science). Science is in every sense a social and historical enterprise. It is about social objectives as well as objects, about social realizations as well as reality.

Neurath drew upon the spirit - if not the letter - of two major turn-of-the-century thinkers: Ernst Mach and Karl Marx. Mach introduced a radical antimetaphysical approach into the analysis of science which Neurath embraced, in part because he believed that metaphysical obscurantism underwrote social institutions that attacked enlightenment values such as equality, freedom and progress. Neurath's aim was to apply the empirical attitude throughout the social sciences. He attacked the distinction drawn by Dilthey, Rickert and Weber between the natural and the social sciences, which rested on non-empirical practice (like the 'empathic' method). A purely empiricist language would represent one big step towards unified science. Methodologically, the job of the social sciences, like the natural sciences, would be to establish correlations - statistical when possible - and to deduce predictions about the future.

Neurath saw in Marx a model of social science without metaphysics and also of unification - of sociology, economics and politics. Marx inspired in him the belief in the social and historical contingency of language and concepts, including those of science ('there is no *tabula rasa*'), and the enlightenment idea that the scientific attitude possesses a practical and socially redemptive (revolutionary) value: the social scientist is also a social engineer. This influence is reflected in Neurath's work in natural economy and his activities as social planner. During the 1910s he articulated, following ideas of Popper-Lynkeus (see Wachtel 1955), an 'ecological' economic programme based on central planning and non-monetary structure. The goal was not the increase of wealth, but the allocation of exhaustible resources and goods in a way that increased the standards of living of individuals; the method, an empirical calculus of needs and satisfaction that introduced 'qualitative exactness' in place of the

quantitative monetary calculations and a central organization in place of a market and monetary unit. The centralized programme required, Neurath realized, a practical, cooperative unification of the sciences: unity at the point of action.

Neurath's ideas also reflect the influence of Henri Poincaré and P.M.M. Duhem (see Conventionalism). A multiplicity of theories can accord equally well with the same data. Science is methodologically open-ended. For Neurath the objective was not to determine which theory is true but which theory, or combination, should be used for a given purpose. This decision is pragmatic: the social scientist is to examine all possible theories and predictions that fit the data, in order, like the engineer, to design (social) machines that have never yet been built.

Neurath rejected all pictures of 'ideal' science as gross metaphysics. His attention to the inextricable link between science and society had several consequences: the amount of knowledge available can never be exhaustive; the uncertainty involved in justifying decision-making 'scientifically' can only be honestly and rationally eliminated through extra-empirical 'auxiliary' motives (to deny this limitation in the power of scientific justification amounts to 'pseudorationalism'); the empirical language of science cannot be a precise and atomic Machian one, on pain of losing descriptive, predictive and explanatory power; the introduction of vague, ambiguous terms into the 'physicalist' language is inevitable; abstract analysis prompts the adoption of a multiplicity of conventional idealized concepts - social factors or indicators - which are value-laden and historically contingent.

3 Scientific language and scientific method: the Vienna Circle and Neurath's logical empiricism (1931-5)

Neurath's later views on the language and method of science represented his simultaneous response to problems in the social sciences and to problems addressed by the Vienna Circle between 1928 and 1934, and by Karl Popper (see Vienna Circle §§2-3). A primary aim of the Vienna Circle was to account for the objectivity of scientific knowledge claims without resort to metaphysics. The method was to investigate the logical and linguistic frameworks of scientific knowledge (the linguistic turn). The 'orthodox' position was that revisable theoretical scientific statements stand in appropriate logical relations to unrevisable elementary observation statements (the data), called 'protocol statements'.

Neurath took the objectivity of scientific knowledge to be provided by the public and social nature of its representations and rules for acceptance. By 1931 his proposed scientific language was 'radical physicalism': scientific statements must speak of material things (not necessarily from the domain of physics) in space and time. Objectivity and the avoidance of metaphysics require that sentences be compared only with sentences, not with 'reality' ('it is impossible to step outside language'). Protocol statements preserve strict 'linguistic empiricism' by avoiding both reference to 'reality' (contra Schlick and Popper) and to subjective (phenomenalistic) experience (contra Carnap and Schlick). They are not items of personal experience but public reports of scientific observations, like a laboratory notebook. They are thus syntactically complex and 'rich in theory', not atomic and purely observational, unavoidably incorporating into science complex and vague cluster-concepts from natural language that lack the 'ideal' precision of theoretical terms. This makes scientific language a historically provided 'jargon'.

Neurath rejected both Carnap's methods of verification and Popper's method of falsification (see Scientific method). With Duhem he believed first that not one but only groups of hypotheses can be confronted with empirical data, hence leaving undetermined how to assign praise or blame within the group (Duhem-Quine problem), and second, that any number of such groups can always fit the same data (see Quine, W.V.; Underdetermination §3). Moreover, protocol statements are revisable (see Fallibilism). In case of conflict between the prediction of theory and a protocol statement, either the theory or the protocol can be rejected (the Neurath principle). Finally, in many cases the presence of imprecise terms will leave the protocol statements in an indeterminate logical relation to the theoretical ones, thus rendering both verification and falsification logically inconclusive. Neurath concluded that the belief in a general unambiguous scientific method is a 'pseudorational' ideal and that all theory choice is ultimately pragmatic. His views are illustrated with his image of the ship: 'We are like sailors who have to rebuild their ship on the open sea, without ever being able to dismantle it in dry-dock and reconstruct it from its best components' (1983: 92).

4 Unity of science and the encyclopedia-model (1934-45)

The ship metaphor also illustrates Neurath's idea of the unification of the sciences as a historical and communal enterprise. In 1934 he articulated the ideas on the unity of science that had been developing in his works since 1910 (see Unity of science). He opposed the myth of the 'system-model': a unique, axiomatic, deductively closed and complete hierarchy of sciences. Instead he proposed the more realistic 'encyclopaedia-model': the coherent totality of the accepted scientific statements at a given time, in flux, incomplete, not void of imprecise statements and logical gaps, unified linguistically by the physicalist 'jargon', and methodologically by the general use of certain techniques (statistics, probabilities and so on) and the empiricist spirit; on the whole, in Neurath's terms, like a 'mosaic', an 'aggregation' of the sciences, or an interdisciplinary 'orchestration' of the scientists' efforts.

Neutral monism

Neutral monism is a theory of the relation of mind and matter. It holds that both are complex constructions out of more primitive elements that are 'neutral' in the sense that they are neither mental nor material. Mind and matter, therefore, do not differ in the intrinsic nature of their constituents but in the manner in which the constituents are organized. The theory is monist only in claiming that all the basic elements of the world are of the same fundamental type (in contrast to mind-body dualism); it is, however, pluralist in that it admits a plurality of such elements (in contrast to metaphysical monism).

Historically, neutral monism had its origins in Ernst Mach's sensationalism (see Mach, E.). According to Mach (1885), the relative permanence of both bodies and the ego are due to their being composed of large numbers of elements not many of which are replaced at any one time. He called these elements 'sensations', though the phenomenalist suggestions carried by this term are misleading, for Mach's sensations are neither mental nor physical.

Mach directly influenced both William James and Bertrand Russell, the philosophers most widely regarded as neutral monists. James' early psychological work, notably his *Principles of Psychology* (1890), was explicitly dualist, although his neutral monism began to appear soon afterwards - for example, in his account of colour perception in *Psychology. A Briefer Course* (1892: 332) - and some commentators have suggested the dualism of the *Principles* was merely methodological. James' monism emerges clearly in 'The Knowing of Things Together' (1895), where he claimed (rather loosely) that the object known and the mind that knows it were ' only two names that are given to the one experience, when, taken in a larger world of which it forms a part, its connections are traced in different directions' (1895: 379). For the next couple of years, in classes and notebooks, James developed these ideas into the view, very similar to Mach's, that there was no 'pure ego' and no material substance, only experience. This, however, remained unpublished until, in 1904-5, he wrote most of the essays which were posthumously collected in *Essays in Radical Empiricism* (1912), and which contains his fullest statement of the theory (see James, W. §6).

It seems to have been Russell who coined the term 'neutral monism' in the course of criticizing the theory in 1913. (James always referred to it as 'radical empiricism', though he had applied the term 'neutral' to experiences in notes written in the 1880s.) Russell did not embrace neutral monism until 1919. In doing so he was influenced to lay aside his earlier objections partly by Hume's arguments for the unintrospectibility of the self (which also impressed James), but most importantly by Wittgenstein's (1921) treatment of belief, which 'shows…that there is no such thing as the soul' (see Wittgenstein, L. §§3-5). James' treatment of belief had been a particular target of Russell's earlier criticism and Russell's first work as a neutral monist was an account of belief (Russell 1919; 1925).

Russell treated the theory more broadly in *The Analysis of Mind* (1921), where he attempted to show how both the mind and material objects could be constructed out of elements he called 'events', the differences between mind and matter arising from the irreducibly different types of causal law each obeyed (see Russell §13). As parts of material objects, events were related by physical causal relations expressed ultimately by differential equations; as parts of the mind they were related by 'mnemic' causal laws, in which a past state of the mind is among the proximate causes of its current state. Although Russell changed details in subsequent works, he never abandoned this general picture (Russell 1956).

In developing his theory, Russell was influenced by recent advances in physics (especially as interpreted by the subjectivist philosophy of A.S. Eddington) and by behaviourism. He said that modern physics had shown matter to be less material than formerly supposed, while modern psychology had shown mind to be less mental. He thought of neutral monism as the natural outcome of these two developments. Despite the evident influence of behaviourism, he rejected the behaviourist attempt to reduce mental phenomena to physical ones. Indeed, Russell insists that mental states, despite their status as logical constructions, are causally efficacious. This has led Baldwin (1995) to suggest that Russell's neutral monism is best seen as an early form of functionalism.

Historically, however, the most obvious heir of neutral monism was the brain-mind identity theory. Here,

neurophysiology takes the place of behaviourist psychology and the account is (typically) given a more materialist slant than the neutral monists would have accepted. None the less, many neutral monist ideas reappear in the identity theory, as identity theorists have acknowledged (Feigl 1967).

Neutrality, political

The principle of political neutrality, which requires the state to remain neutral on disputed questions about the good, is an extension of traditional liberal principles of toleration and religious disestablishment. However, since neutrality is itself a contested concept, the principle remains indeterminate: is it, for example, a requirement of neutral reasons for legislation (or neutral legislative intentions) or is it a more exacting requirement of equal impact in so far as legislative consequences are concerned? The answer must surely reflect the deeper values that are used to justify the neutrality principle. This raises further problems, however. If the principle is based upon certain value commitments - such as the importance of equality or individual autonomy - then it cannot require us to be neutral about all values. It requires some sort of distinction between principles of right (of which neutrality is one) and conceptions of the good (among which neutrality is required). Critics believe that liberal principles of right are symptomatic of a deeper liberal bias in favour of individuality as a way of life. Perhaps liberals should embrace this point, and accept that the neutrality they advocate is quite superficial compared to the depth of their own value commitments.

1 The neutrality principle

In recent political philosophy, the idea of neutrality has been used by Bruce Ackerman, Ronald Dworkin, John Rawls and others to express a liberal position concerning the possibility of bias or commitment on the part of the state in ethical and religious controversies. The citizens of modern pluralist societies disagree on almost everything, but particularly on issues of faith, philosophy and value. The principle of political neutrality requires the state to stay out of all such controversies, and to refrain from throwing the weight of its authority - or worse still, the coercive power at its command - behind any particular view about what makes life worth living.

2 Defending political neutrality

Neutrality may be understood as a reformulation and extension of the traditional principles of religious toleration and disestablishment. Liberal philosophy has always involved an affirmation of political secularism and a rejection of the idea of a confessional state. Political neutrality extends that to encompass the rejection not just of religious establishment, but of ethical perfectionism also (see Perfectionism; Toleration).

The extension is motivated in part by a sense that people’s individual ethical values play much the same role in their lives as their religious convictions. To impose a religious orthodoxy is to strike at the heart of a person’s freedom, for it threatens to displace the criteria which they regard as most important in organizing and disciplining their life. For many people, however, this central role is played not by religious beliefs but by ethical convictions. The broader doctrine of neutrality therefore requires the state to stand back and let people live their individual lives on whatever terms they choose, whether or not those terms have the aura of sanctity associated with religion.

Neutrality can also be defended by arguing that the means which the state characteristically uses to achieve its goals - namely, force and the threat of legal sanctions - are inappropriate for promoting religious or ethical objectives. Proponents of religious toleration such as John Locke believed that a faith imposed coercively from the outside was as good as no faith at all - ’I cannot be saved by a religion that I distrust, and by a worship I abhor’ (1689: 32) - and the development in the nineteenth and twentieth centuries of the idea of ethical individuality led to a similar conclusion about values generally. As Ronald Dworkin put it: ’No life is a good one lived against the grain of conviction. It does not help someone else’s life but spoils it to force values upon him he cannot accept but can only bow before out of fear or prudence’ (1993: 168).

Alternatively, neutrality may be defended on pragmatic or consequentialist grounds. It has not been our experience that those who wield governmental power are endowed with profound ethical insight. In the real world, non-neutral government may well lead to the inculcation and enforcement of superficial or inappropriate ethical standards. More affirmatively, defenders of neutrality may appeal to the case made by J.S. Mill in the second chapter of *On Liberty* (1859), where he argued that the existence of a diverse array of ethics and lifestyles, competing with one another in the marketplace of ideas, is the best way of arriving at the truth, if there is any truth, about the good for human beings. Non-neutral action on the part of the government amounts to loading the dice in favour of one view or set of views in a way that is likely to distort the market-like processes whereby truths and

half-truths are winnowed out from error.

3 Intentions, reasons or consequences?

The justification of the neutrality principle is crucial for our understanding of what, exactly, it requires. Does neutrality simply mean *not taking sides*, or does it mean *going out of one's way to ensure that one does not have an unequal impact*, in the struggle or controversy in which one is supposed to be neutral? Is the liberal state supposed to be neutral in virtue of its intentions or neutral in virtue of the consequences of its laws and policies?

A number of writers - for example, Alan Montefiore (1975) and Joseph Raz (1986) - have interpreted liberal neutrality as concerning primarily the consequences of legislative action. For example, the legislator must take care that the laws do not increase the chances of a hedonistic lifestyle flourishing at the expense of adherence to traditional Christian values. It must enhance or retard the prospects of these lifestyles to the same degree. But this conception gives rise to a number of difficulties. It involves the postulation of some baseline, relative to which differential effects of state action may be measured. And in practical terms it is a very difficult requirement to live up to, because it is so hard to predict what the effect of a law is going to be on lifestyles and mores. If that is how neutrality were to be understood, we should have grave doubts about whether it was ever reasonable to require legislators to be neutral.

Instead of neutrality of impact, the liberal may be talking about neutrality of intention - that is, neutrality in relation to the motives and reasons that the legislator uses to justify the laws. On this account, the fact that a law against Sunday trading would accord with the requirements of a Sabbatarian faith is not a good reason for having such a law; but the fact that it is necessary to prevent shop employees from being overworked may be. The latter reason can be a good reason, and the legislation neutral on that account, even though the law undoubtedly benefits Sabbatarianism over other sects.

This interpretation also faces difficulties however. It is often hard to determine the real intentions behind what lawyers would call a 'facially neutral' statute; a law banning animal sacrifice might be promulgated in the name of public health, but what if some of the lawmakers voted in favour of it because of their antipathy to an animal sacrifice cult? It may be wiser to reformulate neutrality of intention in terms of a principle governing what counts as a good reason for a law or policy. Such a principle would not condemn a piece of legislation if there were in fact neutral reasons in favour of it, whether or not those reasons actually figured in the conscious intentions of the lawmakers.

Which of these conceptions - neutral impact or neutral reasons - should the modern liberal adopt? This must depend on the grounds upon which neutrality is ultimately valued. For example, the Lockean argument about the impossibility of coercing religious faith may yield or justify one conception of neutrality - neutrality of reasons - since it is only the use of coercion to *achieve* religious objectives that is said to be self-defeating. The 'marketplace-of-ideas' argument, on the other hand, may be more congenial to consequentialist concerns. If ethical diversity is valued as a medium in which truth can emerge and progress be made, then we ought to be careful that our political action (whatever its intentions) does not accidentally diminish the diversity of lifestyles.

Something similar applies to the question of non-coercive state action. Is the state required to be neutral in everything it does, or only in its use of force? In England, there is an established state Church, but nowadays no one is obliged to belong to it. Does this violate the neutrality constraint? What about the official institution of (heterosexual) marriage? What about government subsidies to the arts? These policies and institutions do not compel any citizen to do anything in particular, but arguably they still represent the state taking sides in ethical and religious disputes. Can the liberal principle be violated then in this purely symbolic way? It is impossible to find answers to these questions by considering the word 'neutrality' (or, for that matter, the word 'coercion'). The answers must be dictated by the deeper concerns that lie behind our choice of this particular terminology in which to phrase liberal commitments.

4 The distinction between the right and the good

The move from religious toleration to a broader neutrality about values generally poses one other difficulty for liberal political theory. Liberals believe that governments are set up to do justice, to respect rights, to promote the general welfare and to protect freedom. Thus they cannot hold that the state should be neutral in relation to *all*

moral values. After all, neutrality is itself a value: it is a normative position, a doctrine about what legislators and state officials ought to do. Liberals favour neutrality, in Ronald Dworkin's words, 'not because there is no right and wrong in political morality, but because that is what is right' (1978: 142).

It follows that a principle of political neutrality has to be able to justify certain discriminations among values or principles. We have to be able to distinguish value controversies in which the liberal legislator is required to get involved (such as controversies about justice), from those value controversies in which they are required by the principle not to get involved (such as controversies about lifestyle, sin or salvation). The distinction is sometimes characterized in terms of the difference between 'the right' and 'the good' (see Right and good). Neutrality itself and the principles associated with it, such as justice, freedom and individual rights, are principles of political right: their point is to define a framework within which individuals ought to be able to pursue any conception of the good they please. The conception they choose must of course fit within the framework of right, for the framework exists in order to ensure that each person's pursuit of the good (as they see it) is compatible with everyone else's pursuit of the good (as they see it). In this sense, the right is said to be prior to the good, even though the right exists in order to accommodate the good.

But the distinction between the right and the good has itself been subject to heavy criticism, most notably by Michael Sandel (1982), Charles Taylor (1985) and other communitarian writers (see Community and communitarianism §2). They doubt whether any sensible system of right can be defined without reference to a determinate conception of human good: how, for example, can we define a set of rights to cope with the fact of our mutual vulnerability, without some detailed account of what counts as harm and thus some correlative account of interests, needs, health and a person's good? They also note that many people's conceptions of the good life already involve a view of the good society and they may therefore already implicate principles of right: think of an Englishman yearning for a life of traditional service in the established Church, or an Algerian who believes that the practice of his religion is impossible except under a system of Islamic law. Since the liberal doctrine directly challenges these aspirations, it is evidently *not* neutral between all conceptions of human fulfilment, but only (or at most) between those that fit a certain individualistic pattern.

This is not a surprising result. Even the old principle of toleration never claimed to be neutral between all religions: it condemned human sacrifice, the torture of heretics and compulsory tithing, even though these were - strictly speaking - religious practices. It was neutral only between non-coercive faiths. The liberal proponent of political neutrality rejects (and refuses to accommodate) communitarian conceptions of the good for similar reasons.

Still, the critics are right to insist that the liberal framework of right itself embodies certain assumptions about the good. Liberals believe that the shaping of human lives by the individuals who are living them is a good thing, and so they adopt principles of right (including the principle of neutrality) which seek to minimize the coercive impact of other people's views on that process. It is true that some individuals choose to shape their lives (or would like to shape their lives) in accordance with a communitarian conception. But that choice amounts in part to a proposal to govern or interfere with others' shaping of their lives, and this the liberal cannot tolerate. In other words, far from the liberal being required to be neutral between communitarian and non-communitarian conceptions of the good, the liberal's adoption of the neutrality principle is an expression of opposition to the very idea of a communitarian conception of the good.

Newman, John Henry (1801-90)

John Henry Newman was the principal architect of the Catholic revival (the Oxford or Tractarian movement) within the Church of England in the 1830s, and went on to become probably the most seminal of modern Roman Catholic thinkers. Although primarily a theologian, Newman regarded his defence of religious belief in terms of a philosophical justification of non-demonstrable certainty as his most important life work.

Newman was born in London, the elder son of a banker. Elected a fellow of Oriel College, Oxford, in 1822, he became vicar of the university church of St Mary the Virgin in 1828. The five sermons he preached there between 1839 and 1841 on the relation of faith to reason, published in*Sermons, chiefly on the Theory of Religious Belief, preached before the University of Oxford* (1843), are a brilliantly original challenge to the received Lockean understanding of rationality. His defence of the reasonableness of religious belief, which he completed in *An Essay in Aid of a Grammar of Assent* (1870), involves an epistemology which gives both works a wider philosophical significance.

Newman's reception into the Roman Catholic Church in 1845 was followed by the publication of the *Essay on The Development of Christian Doctrine*, his most famous theological work which itself presupposes the anti-Enlightenment theory of knowledge he had sketched in the *Sermons*. Founding President of the new Catholic University of Ireland from 1851 to 1858, Newman's *The Idea of a University* (1873) propounds a philosophy of education concerned with the development of the whole mind rather than only those faculties of utilitarian value. Created a cardinal in 1879, he died in Birmingham in 1890 at the Oratory he had founded there.

The target of the *Sermons* is essentially the restriction of reason to Cartesian rationalism and Lockean empiricism, that is, the assumption that knowledge must either be deduced from logical, a priori truths or derived a posteriori from sense experience by induction. Newman argues that religious faith is only a particular instance of the many perfectly reasonable convictions which we reach in a variety of areas. This kind of reasoning depends not so much on specific arguments and evidence as on pre-existing assumptions and expectations. Someone may legitimately reason in this informal sense without necessarily being able to provide any analysis of their reasoning or even produce their reasons. Thus people may argue badly and yet reason perfectly well. In some kinds of reasoning, and especially in matters of religious belief, the moral factor is especially important because it largely determines the relevant underlying assumptions that in turn form the actual reasons for believing something to be true. Newman thought that the philosopher and the factory worker who are believers share the same 'antecedent probabilities', which in turn rest on the same 'first principles'. The fact that people may not be able to state clearly what they believe and why is because of the distinction between what Newman calls 'explicit' and 'implicit' reasoning. Nor is there one single model of informal reasoning, since there are as many different types of reasoning as there are subjects on which to reason.

If religious belief involves the same kind of informal reasoning that we unhesitatingly employ in other intellectual matters, still the question remains whether certainty is possible and how it differs from the objective certainties of logically necessary propositions and empirically verifiable factual statements. The *Essay in Aid of a Grammar of Assent* is Newman's final attempt to answer the problem. He begins by distinguishing between the assent one makes to a proposition and the conclusion one draws from an inference: assenting and inferring are thus two distinct kinds of activity, however close they may sometimes seem to be. Assent may be 'notional' or 'real', depending on whether the apprehension of a proposition is notional or real. Newman's usage is confusing because, though 'notional' seems to mean what is abstract or general and 'real' what is concrete and individual, nevertheless the distinction is not in fact between sense perceptions and mental abstractions but between experiential and non-experiential knowledge. For one can give a real assent to an apparently abstract idea if that idea becomes a real 'thing' in the imagination (an 'image'), because one then grasps the force of the idea in an experiential and personal way. Indeed, a mental act may bring before the mind a more vivid image than a sensible object. Thus Newman's argument from conscience for the existence of God is that the intimations of conscience are the echoes of a magisterial voice suggestive of a God of whom we gain a real image from and in these dictates of conscience.

Given that assent is not simply the conclusion to an inference (from which it is distinct), then it does not follow, as

Locke claimed, that the only certainty is logical certainty. Propositions that are true by definition normally command assent, but even here assent may be withheld until the conclusion is accepted. Where formal logical inference is impossible, Newman argues that it is the cumulation of probabilities which leads to certainty (see Butler, J.). But assent to the truth of nonlogical propositions involves personal judgment as the mind evaluates both the strength of the individual probabilities and their combined strength. This judgment, which is akin to Aristotle's *phronesis*, Newman calls the 'illative sense', and it operates more or less implicitly and instinctively, without formal verbal analysis.

In his sensitivity to the actuality and complexity of human rationality and its linguistic expression, Newman clearly anticipates the central concerns of the later Wittgenstein. The other factor which has given his epistemology a new significance is his refusal to take the path of Schleiermacher in conceding to science all factual knowledge and claiming for religious utterances merely emotional, imaginative and existential significance; he has found unexpected support from modern philosophers of science who, while accepting the validity of scientific method, nevertheless recognize that the truth claims of science are not as self-evident and unproblematic as used to be assumed.

Newton, Isaac (1642-1727)

Newton is best known for having invented the calculus and formulated the theory of universal gravity - the latter in his Principia, the single most important work in the transformation of natural philosophy into modern physical science. Yet he also made major discoveries in optics, and put no less effort into alchemy and theology than into mathematics and physics.

Throughout his career, Newton maintained a sharp distinction between conjectural hypotheses and experimentally established results. This distinction was central to his claim that the method by which conclusions about forces were inferred from phenomena in the Principia made it 'possible to argue more securely concerning the physical species, physical causes, and physical proportions of these forces'. The law of universal gravity that he argued for in this way nevertheless provoked strong opposition, especially from such leading figures on the Continent as Huygens and Leibniz: they protested that Newton was invoking an occult power of action-at-a-distance insofar as he was offering no contact mechanism by means of which forces of gravity could act. This opposition led him to a tighter, more emphatic presentation of his methodology in the second edition of the Principia, published twenty-six years after the first. The opposition to the theory of gravity faded during the fifty to seventy-five years after his death as it fulfilled its promise on such issues as the non-spherical shape of the earth, the precession of the equinoxes, comet trajectories (including the return of 'Halley's Comet' in 1758), the vagaries of lunar motion and other deviations from Keplerian motion. During this period the point mass mechanics of the Principia was extended to rigid bodies and fluids by such figures as Euler, forming what we know as 'Newtonian' mechanics.

1 Life

Isaac Newton entered Trinity College Cambridge in 1661, and began investigations of mathematics in 1664. These investigations culminated two years later in the binomial theorem and the fundamentals of the calculus. During the so-called *annus mirabilis* of 1666, while the university was closed because of the plague, and in the years immediately following, he extended his mathematical work; he also conducted optical experiments and worked on several basic problems in mechanics, including impact and circular motion. He became Lucasian Professor of Mathematics at Cambridge in 1669.

Although some of Newton's mathematical manuscripts were in circulation, yielding him some renown, his only notable publications before the *Principia* were a series of communications in the *Philosophical Transactions* of the Royal Society from 1672 to 1676 on his experiments on light and colours and the reflecting telescope. The debate which this work provoked led Newton to begin articulating what he called his 'experimental philosophy', which focused on *establishing* propositions by means of experiment.

In an exchange of letters in late 1679, Robert Hooke, himself an eminent scientist, asked Newton to use his mathematical methods to determine the trajectory of a body under a combination of inertial motion and an inverse-square force directed towards a central point - that is, the force Newton later named 'centripetal'. But the intense effort that culminated in the publication of the *Principia* (1687) did not begin until 1684, after a visit from young Edmond Halley, who later became Astronomer Royal.

Newton spent most of the years after 1689 in London. He was elected to represent Cambridge University in Parliament in 1689 and again in 1701, the year in which he resigned his professorship. He became Warden of the Mint in 1696, and Master of it in 1699. In 1703 he became President of the Royal Society, a post he held until he died. He was knighted in 1705.

During his London years Newton engaged in an acrimonious dispute with Leibniz over who had priority for inventing the calculus. One element fuelling this dispute was Newton's failure to publish his work, save for a three-page summary of a handful of results in Book II of the *Principia*. His first formal publications on the calculus appeared in 1704, when two earlier manuscripts were included as supplements in the first edition of the *Opticks*. (A Latin edition of the *Opticks* appeared two years later.)

Newton gave some thought to a restructured edition of the *Principia* in the early 1690s. But the second edition was not published until 1713, after four years of effort under the constructively critical eye of its editor, Roger Cotes. A third edition followed in 1726. These editions sharpened the contrast between his approach and that of Leibniz and

the Cartesians. The second English edition of the *Opticks* (1717/18) included Queries that summarized his conjectures on atomism. These Queries end with a concise statement of his method for establishing scientific knowledge on the basis of experiment and induction; so too does his final riposte in the priority dispute with Leibniz, his anonymous 'An Account of the Book Entitled *Commercium epistolicum*'.

2 Experimental philosophy in the light and colours debate

Newton's 1672 paper on light and colours reported only a small fraction of the optical experiments he had conducted. The debate it initiated concerned what the reported experiments had established. According to Newton, these experiments had conclusively shown that the oblong shape of the image cast by sunlight that has passed through a round hole and has then been refracted by a prism is caused by sunlight's consisting of rays that are refracted in different degrees by the prism. (The correspondence between these different refrangibilities and different colours led Newton to invent the first reflecting telescope, which eliminates the problems of chromatic aberration that had marred the refractive telescopes of the era.)

Hooke, interpreting Newton as claiming that the experiments established a corpuscular theory of light, insisted that a wave theory could account for the results just as well. Newton responded that the hypothesis that light is a body was put forward only as a conjecture suggested by the experiments, and not as part of what he claimed to have been established by them. He granted that Hooke's wave hypothesis could explain the conclusion the experiments had established; but this conclusion spoke of light only abstractly as 'rays' propagating in straight lines from luminous bodies, with no commitment to any specific 'mechanical' hypothesis.

His Dutch contemporary, Christiaan Huygens argued that Newton had failed to show the nature and difference of colours because he had offered no 'hypothesis by motion' to explain them. Newton responded that he ' never intended to shew, wherein consists the nature and difference of colours, but only to shew that *de facto* they are original and immutable qualities of the rays which exhibit them' (1958: 144).

Newton's contemporaries had trouble understanding his attempt to construe light rays abstractly in a way that would allow experiments to decide claims about them - this, independently of any mechanical account of light. In his replies, Newton outlined how, according to his experimental philosophy, diligently establishing properties of things by experiment takes precedence over framing hypotheses to explain them. Yet he also made clear that the propositions he regarded as conclusively established by experiment were nevertheless subject to correction based on detailed criticism of the experimental reasoning that had established them or on further experimental results challenging them (see Optics §§1-2).

3 Space, time and the laws of motion

Two aspects of the *Principia* provoked philosophical controversy in the decades following its publication: first, the appeal to absolute space and motion, and second, the insistence on establishing properties of gravity, especially its universality, without appeal to any mechanical hypothesis that could begin to explain how gravity is produced.

The *Principia* opens with two short sections, 'Definitions' and 'Axioms, or Laws of Motion', that have drawn philosophical fire ever since. The distinctions between absolute and relative time, space and motion are drawn in the first of these, following his introduction of the concept of mass and definitions pertaining to quantity of motion and force. For Newton, the distinction between absolute (or true) and relative (or apparent) motion is primary, and the parallel distinctions concerning space and time serve mostly to support this one (see Mechanics, classical; Space §§2-3). Newton was acutely aware of the empirical difficulties raised by such distinctions:

> It is certainly very difficult to find out the true motions of individual bodies and actually to differentiate them from the apparent motions, because the parts of that immovable space in which the bodies truly move make no impression on the senses. Nevertheless, the case is not utterly hopeless. For it is possible to draw evidence partly from apparent motions, which are differences between the true motions, and partly from the forces that are the causes and effects of the true motions …. But in what follows, a fuller explanation will be given of how to determine true motions from their causes, effects, and apparent differences, and, conversely, how to determine from motions, whether true or apparent, their causes and effects. For this was the purpose for which I composed the following treatise.

(Newton 1687: Scholium to Definitions)

The reference here is to the laws of motion and their corollaries, which immediately follow this last remark, as well as to the ninety-eight demonstrated Propositions of Book I and the fifty-three of Book II.

Like Descartes, Newton appealed to forces to distinguish true from apparent motions. And, again like Descartes, the true motion of greatest importance to him in the sequel is curvilinear motion, most notably the true motion of the planets that would distinguish between their equivalent relative motions in the Copernican and Tychonic systems. Unlike Descartes, however, Newton refused to offer hypotheses concerning the forces in question (see Descartes, R. §11). He required that the forces be inferred from phenomena with the help of the mathematical principles of Books I and II, many of which licence inferences from observed motions to measures of force. Inconsistencies among the inferred quantities of force or the motions subsequently inferred from them would indicate a failure to be dealing with true motions. But this is an empirical question, to be decided by carrying out the investigation of motions under forces to its fullest extent, insisting on no less than complete agreement between observed and calculated motions. Thus, the successes, and also the limitations, of the appeal to absolute space, time and motion were, for Newton, empirical issues that the long-term development of an exact science of motion would decide, and not something he thought was open to a priori resolution.

4 Inferences from phenomena and rules of natural philosophy

The Propositions of Books I and II are powerful resources for establishing conclusions about forces from phenomena of motion. For example, according to Propositions 1 and 2, Kepler's area rule holds if and only if the force acting on the moving body is centripetal. A corollary adds that the areal velocity is increasing when the force is off-centre in the direction of motion and decreasing when it is in the opposite direction. *The variation of the areal velocity is thus a measure of the direction of the force*. Similar systematic dependencies are involved in the inferences from Kepler's $3:2$ power rule and the absence of discernible orbital precession to the inverse-square variation of celestial centripetal forces (see Kepler, J.).

Rules of reasoning, which in the second and third editions are singled out at the beginning of Book III under the title *Regulae philosophandi*, strengthen the inferences that can be drawn from phenomena by licensing inductive generalizations (see Scientific method §2). The first two rules, for example, underlie the inference that the force holding the moon in orbit is terrestrial gravity - this, on the basis of the inverse-square relation between the centripetal acceleration of the moon and the acceleration of gravity at the earth's surface. The third rule, appearing for the first time in the second edition, supports the inference that all bodies gravitate towards each planet with weights proportional to their masses - this, on the basis of pendulum experiments and the common acceleration of Jupiter and its satellites toward the sun.

The fourth rule authorizes the practice of treating propositions that are supported properly by reasoning from phenomena as 'either exactly or very nearly true notwithstanding any contrary hypotheses, until yet other phenomena make such propositions either more exact or liable to exceptions'. It was added in the third edition to justify treating universal gravity as an established scientific fact in the face of complaints that it was unintelligible without an explanation of how it results from mechanical action by contact. This rule, and the related discussion of hypotheses at the end of the General Scholium added in the second edition, distinguish Newton's experimental philosophy most sharply from the mechanical philosophy of his critics.

5 Gravity as a universal force of interaction

The systematic dependencies by means of which Keplerian phenomena become measures of celestial forces are one-body idealizations. Universal gravity entails interactions among bodies, producing perturbations that require corrections to the Keplerian phenomena. The *Principia* includes a successful treatment of two-body interactions and some promising, though limited, results on three-body effects in lunar motion. But the full significance of the inferences that could be drawn from universal gravity did not become clear until Clairaut's analysis of the precession of the lunar orbit in 1749, and Laplace's determination in 1785 of the roughly 880-year 'Great Inequality' in the motions of Jupiter and Saturn.

Such successful treatments of perturbations do more than provide corrections to Keplerian phenomena. They also show that Newtonian measurements of inverse-square centripetal forces continue to hold to high approximation in the presence of perturbations. Interactions with other bodies account for the precessions of all the planets except

Mercury. Even in the case of Mercury, the famous 43 seconds-of-arc-per-century residual in its precession yields -2.000000157 as the measure of the exponent, instead of the exact -2 measured for the other planets. That such a small discrepancy came to be a problem at all testifies to the extraordinary level to which Newton's theory of gravity demonstrates an ideal of empirical success.

6 Mathematics

Newton engaged in extensive mathematical research throughout much of the period from 1664 until he left for London in 1696, and even after that he produced new results on some problems. Besides the many lines along which he developed and applied the calculus, he made substantial discoveries in algebra and in pure as well as analytic geometry. The mathematics of the *Principia* is itself a new form of synthetic geometry, incorporating limits. (Contrary to the still-persisting myth, there is no evidence that Newton first derived his results on celestial orbits within the symbolic calculus and then recast them in geometric form.)

Newton's invention of the calculus grew out of his attempts to solve several distinct problems, often employing novel extension of the ideas and methods of others. For example, his initial algorithms for derivatives of algebraic curves combined Cartesian techniques with the idea of an indefinitely small, vanishing increment. He exploited a method of indivisibles that John Wallis had used in obtaining integrals of algebraic curves; but he reconceptualized the method to represent an integral that grows as the curve extends incrementally, and then joined this with the binomial series to yield integrals via infinite series of a much wider range of curves. Geometrical representations of these results revealed the inverse relation between integration and differentiation. Then, adapting his Lucasian predecessor Isaac Barrow's idea to treat curves as arising from the motion of a point, Newton recast the results on derivatives, replacing indefinitely small increments with his 'fluxions'. The first full tract on fluxions, 'To Resolve Problems by Motion', is dated 1666, but the first manuscript to circulate was *De analysi per aequationes infinitas* of 1669.

Mathematicians in England used Newtonian methods and notation into the nineteenth century. But the Leibnizian tradition had gained so much momentum by the time Newton's works appeared that the calculus, as we know it, stems far more from that tradition. Ironically, it was such figures as the Bernoullis and Euler (belonging to the Leibnizian tradition) who recast the *Principia* into the language of the calculus.

7 Studies in alchemy and theology

Newton's unpublished manuscripts contain voluminous studies on alchemy, theology, prophecy and Biblical chronology. His alchemical work led to a number of elaborate chemical experiments carried out from the mid-1670s until 1693. His notes from these efforts display his great skill as an experimenter, but they appear to include nothing that would have altered the course of chemistry had they become public at the time (see Alchemy).

He first became preoccupied with theology in the early 1670s, probably in response to the requirement that he accept ordination to retain his Trinity fellowship. (He was granted a dispensation in 1675.) By 1673 he had rejected the doctrine of the Trinity and concluded that Christianity had become a false religion through a corruption of the Scriptures in the fourth and fifth centuries. He returned to these studies in subsequent decades, especially in the last years of his life. During his lifetime, however, he conveyed his radical views to only a few. They became widely known only when *Observations upon the Prophecies* was published in 1733.

Recent investigations of the alchemical and theological writings suggest that Newton's hope in natural philosophy was to look through nature to see God, that it was to be part of a larger investigation that would give meaning to life. His engagement with these larger issues may have helped him to free himself from the narrower restraints of the mechanical philosophy.

Nichiren (1222-82)

Fiery prophet, religious reformer, founder of a major religious movement, brilliant preacher and erudite writer, Nichiren is one of Japan's most controversial religious figures. His thought derived from the Tendai tradition, from which he inherited both his veneration of the Lotus Sutra and the idea of an eternal Buddha woven into the stuff of all reality.

Born on the southeastern seacoast of Japan, the son of a fisherman, Nichiren entered a local Buddhist monastery at eleven and was ordained four years later with the monastic name Rencho. He subsequently studied Pure Land and Zen in Kamakura, and Shingon on Mount Kōya. In 1253 he returned to his home temple, changed his name to Nichiren (Sun Lotus), and announced that he would devote his life to ridding Buddhism of the heresy and corruption that had overtaken it. Like many in the Kamakura period, he believed that Buddhism was entering the age of *mappō* (latter days of the Dharma, a period of ten thousand years beginning with the third millennium after the death of the Buddha), which only a faith of the utmost purity could hope to survive.

For Nichiren, the loadstone of that purity was the *Lotus Sutra*, the chanting of whose name (*Namu-myōhō-rengekyō*) and living out of whose teachings alone would insure salvation. Proclaiming himself the embodiment of the original *bodhisattva*, Jōgyō, who had first received that scripture from the Buddha himself, Nichiren took on himself the mission of saving the soul of Japan.

Traditionally Buddhism recognized two means of spreading the Dharma: accommodation (*shōju*) and confrontation (*shakabuku*). In the age of *mappō*, only the latter would do, and Nichiren set out to demonstrate this. He rejected Zen meditation, Pure Land *nenbutsu*, Shingon rituals, and Ritsu (*vinaya*) discipline as diabolical. So sweeping were his condemnations that some contemporary scholars have even questioned whether the sects that venerate him as founder deserve to be called Buddhist at all. Loyalty to the *Lotus Sutra* took precedence over everything else in his life and provoked one conflict after another with civil and religious authorities.

As Nichiren saw it, belief in 'provisional' Buddhas, central to the first half of the *Lotus Sutra*, ended up in superstition for the ordinary faithful and abstract debate for the scholars. Only single-minded faith in the reality of the one, absolute Buddha, central in the second half of the *sūtra*, could awaken the world from its dark ignorance, and only the recitation of the sacred name of the *sūtra* could bridge the gap between the two. Further, since he was persuaded that Japan was destined to replace India as the centre from which Buddhism would spread to the rest of the world, he insisted that the scripture be read not only with the lips but with the whole body: that is, that it lead to the transformation of society. Perhaps the most systematic statement of Nichiren's thought appears in a work entitled *Kanjin honzon shōomacr;((A Clear Mind on Supreme Reality)* and in the graphic portrayal of his *Great Mandala*, both completed in exile in the year 1273.

Nicholas of Autrecourt (*c.*1300-69)

Unlike most of his late medieval contemporaries, Nicholas of Autrecourt did not subscribe to Aristotelianism. Instead, he radically challenged the foundations of Aristotle's metaphysics and epistemology by asking two questions: first, how are we supposed to explain the basic constituents of the world, given that the Aristotelian categories are mere theoretical constructions and not immediately perceivable? Second, what can we know with absolute certitude, given that sense perception - the starting point in Aristotelian epistemology - is fallible and unreliable? Focusing on these two questions, Nicholas elaborated an atomistic metaphysics and defended an epistemology that emphasizes knowledge of a logical principle (the principle of non-contradiction), dismissing all knowledge based on inductive reasoning as uncertain.

1 Life and works

Nicholas of Autrecourt (also Autricuria or Ultricuria), a scholastic theologian and philosopher, was born around 1300 in the diocese of Verdun. He studied at the University of Paris around 1330 and lectured there on Peter Lombard's *Sentences*. In 1340 he was summoned to Avignon to answer charges of heresy. His trial was interrupted by the death of Pope Benedict XII but was resumed under Pope Clement VI, by Cardinal William Curti. In 1346, the papal jury concluded that Nicholas was unworthy to continue his academic career. He was forced to recant many of his philosophical and theological theses and was expelled from the university. In 1347 his works were publicly burned. His appointment as deacon at the cathedral of Metz in 1350 may be seen as an indication that he was no longer considered a heretic. He probably died in Metz in 1369.

Only a small portion of Nicholas' works has been transmitted. Extant works include two complete letters addressed to the Franciscan Bernard of Arezzo, mostly dealing with epistemological problems, along with fragments of seven other letters to Bernard; a letter written to a certain Giles, also concerned with epistemological issues; the treatise *Exigit ordo executionis (The Universal Treatise)*, surviving in a single incomplete manuscript, which is inspired by a decisive anti-Aristotelianism and focuses on metaphysics and natural philosophy; and a short theological question. In addition, the condemned articles contain important information about some of Nicholas' semantic theses.

2 Epistemology

Nicholas' main goal was to defend the possibility of evident, certain knowledge against Bernard of Arezzo's sceptical challenges. According to Bernard, one can never infer '*x* exists' from '*x* is perceived and thought of', because one may have a mere thought object that is not immediately caused by or founded upon a real, actually existing object. For instance, one may think about Caesar although Caesar is not actually existing and may never have existed, or one may have a perception of whiteness although there is no white thing in reality.

In order to reject Bernard's conclusion that no certain knowledge is possible, Nicholas maintained that there is one kind of absolutely certain knowledge (apart from the certitude of faith): knowledge of the principle of non-contradiction (de Rijk 1994: 58). This is the first principle in a negative sense because nothing is prior to it, and the first principle in a positive sense because all other certain knowledge is reducible to it. One can have certain knowledge of an implication (*consequentia*), Nicholas claimed, only if the consequent is identical with or part of the antecedent. Otherwise it would not be evident that the antecedent is inconsistent with the denial of the consequent. For instance, one can have certain knowledge of 'If the house exists, then the wall exists' only if the wall is a part of the house: otherwise it would not be evident that 'If the house exists, then one of its parts does not exist' violates the principle of non-contradiction. Nicholas held that we have to confine ourselves to this basic knowledge if we aim at certitude. From the fact that one thing is known to exist, the existence or non-existence of another thing can never be known with absolute certitude. Nor can one have any certain knowledge based on inductive reasoning: 'In the past, my hand was warmed when I put it toward the fire; therefore it will be warmed now if I put it toward the fire' cannot be known with certitude. My present action is not identical with or part of my past action, and no violation of the principle of non-contradiction results if I say 'Although in the past my hand was warmed when I put it toward the fire, it will not be warmed now when I put it toward the fire'.

It is clear that Nicholas' strict limitation to knowledge of the first principle involves a radical critique of theories of

causality and of induction. Strictly speaking, one can never know that a certain effect *e* is brought about by a cause *c*, and one can never predict that *e* will be brought about if *c*, not hindered by any impediment, will be active. All one can do is have a sense perception of *c* and *e*, and then evaluate whether or not the two contradict each other. Because of this radical claim, Nicholas has been labelled ‘a medieval Hume’ by some modern commentators (Rashdall 1906-7). Yet it is important to see that Nicholas had no sceptical intentions. In pointing out that absolutely evident, though narrowly limited knowledge is possible, he in fact aimed to refute scepticism.

3 Metaphysics

Humans would live better lives, Nicholas polemically claimed, if only they would abandon their studies of Aristotle (de Rijk 1994: 154-5). Aristotle and his successors posited many entities that are mere theoretical constructions and cannot be known with certitude. All we can immediately experience are (1) the objects of our five exterior senses, and (2) our own acts. It is not evident on the basis of (1) that there are entities belonging to the Aristotelian categories (substances, qualities and so on); all we can say is that we have sense experience of constantly changing objects. Nor is it evident on the basis of (2) that there is a soul with three powers. We are only entitled to say that we are aware of inner acts having certain functions (thinking, willing and so on). We have no justification for introducing any concrete or abstract entities beyond the objects of our external or internal experience.

Nicholas also harshly attacked the Aristotelian thesis that there is generation and corruption of things. We do not know with certitude that substances or qualities come into and go out of existence; all we know is that things we perceive appear to change. This appearance can be explained in terms of an atomistic theory, wherein the world consists of eternally existing particles which constantly change their constellation; when things appear to change, or to come into or go out of existence, there is nothing but aggregation and separation of the atomic particles (see Atomism, ancient).

In this manner, Nicholas broke radically from the then prevailing Aristotelian metaphysics. He used atomism as a decisive tool in his natural philosophy, in particular in his theory of the continuum. Contrary to many Aristotelians, he held that a continuum is not composed of infinitely divisible parts, but that it has atomic particles as its ultimate constituents. Although radical, however, this thesis was not completely new; indivisibilism can be traced back to several early fourteenth-century authors including Henry of Harclay, Walter Chatton and Gerard of Odo.

4 Semantics

No work documenting Nicholas’ semantics has been transmitted, but some of his most controversial theses can be reconstructed on the basis of the condemned articles. Article 1.1 states: ‘I have said and written that this sentence "Man is an animal" is not necessary according to faith, not paying attention for the moment to the necessary linkage between the foresaid terms’ (de Rijk 1994: 146). This article is clearly connected with a famous late medieval sophism that raises the problem of whether the truth of a sentence requires the actual existence of the things referred to by the terms of the sentence. Some authors (for example, Roger Bacon and Boethius of Dacia) gave an affirmative answer: if no man exists, they claimed, the term ‘man’ has no reference, and if there is no referent, the sentence is false. Therefore the sentence is not necessarily true. Others (such as Siger of Brabant and Robert Grosseteste) held that the terms in this sentence refer not to individual men and animals but to the eternally existing species and genus; therefore ‘man’ always has a referent, even if no man actually exists, and the sentence is necessarily true. Nicholas obviously chose the former explanation, but this was taken to be heretical (and indeed had already been condemned at Oxford in 1277). Contrary to Christian doctrine, the sentence ‘Christ is a man’ is not necessarily true if one claims that terms exclusively refer to actually existing things. During the three days in the tomb Christ was not an actually existing man; therefore the term ‘man’ did not have a reference during this period and the sentence was temporarily false.

Another important semantic issue is raised in Article 16.4: ‘[I have said] that what is signifiable in a complex way (*complexe significabile*) through the sentence "God and creature are distinct" is nothing (*nihil*)’ (de Rijk 1994: 160). This article raises the question of whether the entire sentence signifies an entity that is not reducible to any other entity. Does ‘God and creature are distinct’ signify the state of affairs that God and creature are distinct, something reducible neither to the extramental things (that is, God, creature and their relation) nor to the concepts

of these things? Nicholas clearly gave a negative answer. A state of affairs is nothing: there is no third entity in addition to extramental and mental entities. Thus, Nicholas did not deny the existence of God and creature, as his judges may have thought; rather, he rejected the claim (supported by Gregory of Rimini and other Parisian authors) that a state of affairs is a peculiar kind of thing.

The semantic theses show clearly that Nicholas tackled some of the most prominent problems of his time. Although a radical critic of the dominant Aristotelianism and excluded from the intellectual centre, Nicholas was not simply an academic outsider. Most of his criticisms are developed within the framework of prevailing philosophical doctrines, and attack either the framework itself (especially in epistemology and metaphysics) or some widely accepted theses within it.

List of works

Nicholas of Autrecourt (*c.*1300-69) *Exigit ordo executionis (The Universal Treatise)*, ed. J.-R. O'Donnell in 'Nicholas of Autrecourt', *Mediaeval Studies* 1, 1939: 179-280; trans. L. Kennedy, R. Arnold and A. Millward, *The Universal Treatise of Nicholas of Autrecourt*, Milwaukee, WI: Marquette University Press, 1971.(This edition is taken from the single incomplete manuscript which has survived.)

Nicholas of Autrecourt (*c.*1300-69) Letters, ed. L.M. de Rijk, *Nicholas of Autrecourt: His Correspondence with Master Giles and Bernard of Arezzo*, Leiden: Brill, 1994.(Critical edition with English translation and extensive commentary.)

References and further reading

de Rijk, L.M. (ed.) (1994) *Nicholas of Autrecourt: His Correspondence with Master Giles and Bernard of Arezzo*, Leiden: Brill.(Critical edition of Nicholas' letters with English translation, accompanied by an extensive commentary.)

Imbach, R. and Perler, D. (1988) *Nicolaus von Autrecourt: Briefe (Nicholas of Autrecourt: Letters)*, Hamburg: Meiner.(Contains a reprint of the condemned articles as well as an edition of Nicholas' letters.)

Lappe, J. (1908) *Nicolaus von Autrecourt, sein Leben, seine Philosophie, seine Schriften (Nicholas of Autrecourt, His Life, Philosophy and Writings)*, Beiträge zur Geschichte der Philosophie des Mittelalters 6.2, Münster: Aschendorff.(First edition of all the letters and condemned articles, and also a pioneering study of Nicholas' life and intellectual context.)

Rashdall, H. (1906-7) 'Nicholas de Ultricuria, a Medieval Hume', *Proceedings of the Aristotelian Society* 7: 1-27.(Pioneer study of Nicholas' alleged scepticism.)

Scott, T.K. (1971) 'Nicholas of Autrecourt, Buridan, and Ockhamism', *Journal of the History of Philosophy* 9: 15-41.(Discussion of Nicholas' epistemology in the light of the Ockhamist and Anti-Ockhamist movements in Paris.)

Tachau, K.H. (1988) *Vision and Certitude in the Age of Ockham: Optics, Epistemology and the Foundations of Semantics 1250-1345*, Leiden: Brill.(Chapters 11-12 focus on Nicholas' condemnation in the context of the 1340s and shed new light on the anti-sceptical strategy.)

Thijssen, J.M.M.H. (1990) 'The "Semantic Articles" of Autrecourt's Condemnation', *Archives d'histoire doctrinale et littéraire du moyen-âge* 65: 155-75.(Detailed analysis of most semantic articles; interesting comparisons with fourteeth-century debates.)

Weinberg, J. (1948) *Nicholas of Autrecourt*, Princeton, NJ: Princeton University Press.(Most comprehensive, still important study that takes into account both Nicholas' epistemology and his metaphysics.)

Nicholas of Cusa (1401-64)

Also called Nicolaus Cusanus, this German cardinal takes his distinguishing name from the city of his birth, Kues (or Cusa, in Latin), on the Moselle river between Koblenz and Trier. Nicholas was influenced by Albert the Great, Thomas Aquinas, Bonaventure, Ramon Llull, Ricoldo of Montecroce, Master Eckhart, Jean Gerson and Heimericus de Campo, as well as by more distant figures such as Plato, Aristotle, Proclus, Pseudo-Dionysius and John Scottus Eriugena. His eclectic system of thought pointed in the direction of a transition between the Middle Ages and the Renaissance. In his own day as in ours, Nicholas was most widely known for his early work De docta ignorantia (On Learned Ignorance). In it, he gives expression to his view that the human mind needs to discover its necessary ignorance of what the Divine Being is like, an ignorance that results from the infinite ontological and cognitive disproportion between Infinity itself (that is, God) and the finite human or angelic knower. Correlated with the doctrine of docta ignorantia *is that of* coincidentia oppositorum in deo*, the coincidence of opposites in God. All things coincide in God in the sense that God, as undifferentiated being, is beyond all opposition, beyond all determination as* this *rather than* that*.*

Nicholas is also known for his rudimentary cosmological speculation, his prefiguring of certain metaphysical and epistemological themes found later in Leibniz, Kant and Hegel, his ecclesiological teachings regarding the controversy over papal versus conciliar authority, his advocacy of a religious ecumenism of sorts, his interest in purely mathematical topics and his influence on the theologian Paul Tillich in the twentieth century. A striking tribute to Nicholas' memory still stands today: the hospice for elderly, indigent men that he caused to be erected at Kues between 1452 and 1458 and that he both endowed financially and invested with his personal library. This small but splendid library, unravaged by the intervening wars and consisting of some three hundred volumes, includes manuscripts written in Nicholas' own hand.

1 Biography

Of Nicholas' early life, little is known. He was one of four children born to Johan Krebs and Katharina Roemer Krebs. Still unconfirmed is the speculation that his father, a successful ferryman and hauler of merchandise up and down the Moselle, sent him to Deventer in Holland for part of his primary education. As for higher learning, Nicholas studied the liberal arts at the University of Heidelberg during 1416-7. Subsequently, he transferred to the University of Padua, where he came under the influence of the Italian humanists and acquired familiarity with the latest physical and mathematical theories. At Padua he studied principally canon law, receiving his *doctor decretorum* in 1423. In the spring of 1425 he continued his study of canon law at the University of Cologne where, apparently, he also gave lectures and where Heimericus de Campo introduced him to the ideas of Ramon Llull and Pseudo-Dionysius. In 1425 and 1426 he held benefices from the archbishopric of Trier, and by 1427 he was secretary to the archbishop himself, Otto von Ziegenhain. In 1428 and again in 1435 he was offered a chair in canon law at the University of Louvain, but on both occasions he declined, preferring to continue with his canonical and administrative work on behalf of the archdiocese and - at the Council of Basel - with his work as a member of the Council's committee on matters of faith.

During his 'Basel period' (1432-8, not all of which time he was in Basel) he wrote, among other things, *De communione sub utraque specie (On Communion Using Both the Bread and the Wine)*, against the Hussites, in 1433; *De concordantia catholica (The Catholic Concordance)* in 1433 and *De auctoritate praesidendi in concilio generali (On Presidential Authority in a General Council)* in 1434, both of which concern the demarcation of papal authority; and *De reparatione kalendarii (On Amending the Calendar)* in 1436, a proposal for revising the Julian calendar. At Basel he met John of Torquemada, whose treatise against the Muslims, *Tractatus contra principales errores perfidi Machometi* (Tractate Against the Principal Errors of the Infidel Muhammad) (1459), was to influence his own *Cribratio Alkorani (A Scrutiny of the Qur'an)* in 1461. Also affecting his response to the incursion of Islam into the West were his first-hand experiences of Islam in 1437, while present in Constantinople for two months (24 September-27 November). The delegation to which he belonged had been sent by the minority party of the Council of Basel to encourage both the Byzantine emperor and the Greek patriarch to reunite with the Roman patriarchate. It was on his return voyage from Constantinople, while still at sea, that Nicholas came to embrace the notion of learned ignorance.

Sometime between 1436 and 1440, Nicholas was ordained a priest. On 20 December 1448 he was named cardinal, and to him was assigned, on 3 January 1449, the titular church of St Peter ad Vincula in Rome. Some fifteen months thereafter (23 March 1450) he was designated bishop of Brixen in Tirol, where later his attempts to introduce monastic and diocesan reforms engendered enmity with Archduke Sigismund, whose threats forced him twice to flee to Rome. His death came on 11 August 1464 in Todi, Italy, as he was travelling from Rome to Ancona.

2 Two basic themes

The themes of *docta ignorantia* and *coincidentia oppositorum* were misunderstood by Nicholas' contemporary and adversary John Wenck of Herrenberg, who in *De ignota litteratura* (On Unknown Learning) inveighed against Nicholas' treatise *De docta ignorantia (On Learned Ignorance)*. In a response, *Apologia doctae ignorantiae (A Defence of Learned Ignorance)*, Nicholas made clear that the doctrine of learned ignorance is not intended to deny knowledge of the existence of God but only to deny all knowledge of God's nature (except on the part of God himself). All our discourse about God is metaphorical; moreover, when we are conceiving positively of God, we are obliged to conceive of him in accordance with those metaphors that signify the highest perfections. The doctrine of *docta ignorantia* goes on to teach that the quiddities of created objects are unknowable by us precisely; that is, they are unknowable exactly as they are in themselves. Yet, although the objects are unknowable exactly *in themselves*, the *objects themselves* are not unknowable. Rather, they are apprehensible by us *in coniectura*, Nicholas' expression for what is knowable only imperfectly and perspectivally. The doctrine of learned ignorance constitutes a radical break with the scholastic affirmation of a real, but remote, resemblance between God and his creation. The late scholastic William of Ockham had repudiated the validity of all alleged analogical knowledge of God's nature, though he nonetheless maintained that the predicate 'being' is used univocally in discourse about divine being and created being. By contrast, Nicholas regards even 'being' as an equivocal and metaphorical predicate when used of God.

The doctrine of *coincidentia* does not mean, as in John Wenck's construal of it, that the universe coincides with God, nor does it serve to contravene the Aristotelian principle of non-contradiction within the legitimate domain of that principle's application - that is, its application to the realm of finite affairs. All things are present in God ontologically prior to their creation, as illustrated by an effect's being present in the priority of its cause. But just as, in its cause, an effect is the cause, so in God all things are God rather than being their differentiated, finite selves. Nicholas nowhere teaches, unqualifiedly, that all things are God; indeed, he expressly rejects pantheism and its variants. Though he speaks of God as not *other* than (*non aliud a*) the universe, he does not mean that God is identical with (*non aliud quam*) the universe, but rather that God transcends the domain of comparison with all finite objects.

3 Ontology

Nicholas' ontology has been interpreted along two very different lines. According to one line of interpretation, Nicholas regards finite objects as having no respective positive essence of their own, for God himself is the self-identical essence of each finite thing. Accordingly, the relative identity of each thing is said to consist only in its difference from all other finite things, all such differences being accidental and all relations between these things being internal relations. Thus in this view, propounded in Europe by Heinrich Rombach (1965) and in North America by Thomas P. McTighe (1964), created things are not substances and do not differ from one another substantially. According to the second, more generally accepted line of interpretation - one taking its lead from Nicholas' *Apologia* - some created things are substances, and these do have positive essences of their own. In accordance with their respective essences, finite things differ essentially from one another. God is the Essence of these things in that he is the Essence of the respective essences of these things, even as he is *being* itself (*entitas*), which sustains in existence whatever is *a* being (*ens*). This distinction between *being* and *beings* Nicholas draws from Meister Eckhart; and it is one of the distinctions that influence both Paul Tillich and Martin Heidegger.

In *De filiatione Dei (On Being a Son of God)* 3, Nicholas' likening of all created beings to mirrors that mutually reflect one another prefigures Leibniz's systematic use of a similar theme (see Leibniz, G.W.). Also parallel with tenets in Leibniz are the assertions (1) that each kind of thing - though not each individual within that kind - is as perfect as that kind of thing can be and (2) that physical objects (which, for Leibniz, are 'well-founded appearances') are, in principle, infinitely divisible. Nicholas' various utterances regarding *nihil* (not-being) in

relation to *esse* (being) have struck some interpreters as inchoately Hegelian, in a dialectical sense (see Hegelianism). Others have seen Nicholas not as working with logico-ontological categories but as being a metaphysical nominalist. In the last analysis, his theory of universals (if not his theory of transcendentals) must be reckoned to be a moderate realism that is cognate with that of Aristotle and Aquinas.

4 Cosmology

At times Nicholas denies that the universe is finite and also denies that it is infinite; at other times he asserts that it is both finite and infinite. It is not finite, he tells us, in that it is not physically limited by anything outside its dimensions; on the other hand, it is finite in that it has a definite measure, known to God alone. In other words, the universe is finite but unbounded; yet, Nicholas terms it *privatively* infinite, in contradistinction to God, who is *negatively* infinite, since he is not even conceivably limited.

Because there is no perfect precision in the world, explains Nicholas, the universe's circumference is not perfectly spherical, nor is the earth a perfect sphere. Consequently, neither the universe nor the earth has an exact physical centre and, thus, the earth is not the fixed centre of the universe. Indeed, the earth is not stationary but, like all stars and planets, has a circular movement of its own, though this movement is undetectable by us, its inhabitants. Likewise, the earth appears to us to be at the centre of the universe, and we infer that the 'fixed' stars are at the outer circumference. However, these stars also have inhabitants, who will judge themselves to be at the centre and the earth to be on the periphery. Furthermore, both the earth and the moon, as also the other heavenly bodies, emit a light and a heat of their own, even though both the earth and its moon also reflect the sun's light and heat. Nicholas' cosmological claims do not anticipate those of Copernicus, but they do deviate in important respects from those of Aristotle and Ptolemy.

5 Epistemology

In *De visione Dei (The Vision of God)* 24, Nicholas states that 'there cannot be in the intellect anything which is such that it was not first in the senses', thus rejecting the notion of innate concepts. Yet, in *Idiota de mente (The Layman on the Mind)* and elsewhere, he allows that the mind, through construction, can make concepts of things (such as a spoon) whose forms are not found in nature. Moreover, the mind has an innate power of judgment (*vis iudiciaria*) by which to weigh the strength of rational considerations and through which it is familiar, a priori, with basic moral principles (*Compendium* 10). Although human beings cannot know the exact quiddity of any given thing, they do nevertheless perceive the things themselves, through the medium of sensory images and conceptual forms. In places, Nicholas emphasizes (1) sensory and conceptual perspectivity, (2) the role of reason (*ratio*) as synthesizer and (3) the conditioning operations of the intellect (*intellectus*). (One must be careful, however, not to exaggerate his dim prefiguring of Kant.) Mathematical knowledge he regards as a priori and certain, because mathematical entities are conceptual entities elicited from, and known in a precise way by, our reason (*De possest (On Actualized-possibility)* 43-4). In *Idiota de mente* 6 he seems to endorse the doctrine that these conceptual numbers are 'images', as it were, of God's thought. The mathematical puzzle with which he is principally preoccupied is that of how to square the circle: in other words, how in a finite number of steps to construct, using only an unmarked straight-edge and a drawing compass, a square whose area is equivalent to that of a given circle.

6 Christology

Nicholas' Christology is orthodox, inasmuch as he considers Jesus to be the incarnate second member of the Trinity, uniting in his divine person his divine nature with a human nature. In accordance with the divine nature, Jesus is the Absolute Maximum; in accordance with his human nature, he is the contracted maximum individual. The Absolute Maximum is Infinity itself and is such that nothing greater than it can be conceived; the contracted maximum is an individual creature that is of maximum perfection within its kind. (By 'contracted', Nicholas means restricted, differentiated or delimited, so as to be *this* thing and not *that* thing.) Thus Jesus' human nature is the perfection of the possibility of human nature. Furthermore, since human nature, which consists of a body and a rational soul, is a middle nature - a nature in between the higher intelligible natures (namely, angels) and the lower corporeal natures (namely, brute animals and non-animate things) - Jesus' perfect human nature is 'the fullness of all the perfections of each and every thing'. Thus, reminiscent of Eriugena's *De divisione naturae*, the perfect world that went forth from God in creation is reunited to God through the subsumption of Christ's human nature in

his divine nature.

7 Ecclesiology

In *De concordantia catholica*, Nicholas seeks to demarcate the respective authority of a universal council and of the pope. A universal council (in contrast to a patriarchal council) is one to which bishops and select ecclesiastics from all five patriarchates have been called - a call issued usually by a patriarch or a patriarchal council, or an agent of either. A universal council may depose a heretical pope. A decision (on matters of faith) reached with a high degree of agreement by a universal council is more trustworthy than would be a decision on such matters by the pope alone. Yet, on matters of faith, the pope's consent as well as the council's is required for declaring a decision infallible. Nicholas speaks of degrees of infallibility, and he relates these to degrees of consensus: the greater the consensus within a universal council and beween this council and the pope, the greater the infallibility of the decision reached. Nicholas later was to abandon his claim that the authority of a universal council in which there is substantial agreement is superior to the pope's authority.

8 Ecumenism

The dialogue *De pace fidei (On Peaceful Unity of Faith)* serves to challenge the various leaders of the different religions to adopt *religio una in rituum varietate*, a common religion that admits of diverse rites. The spirit of this 'ecumenism' is reinforced in *Cribratio Alkorani*, where Nicholas seeks to find common ground between Christianity and Islam. Yet Nicholas' is not a genuine ecumenism, for he aims to show how other religions can be led to discern the truth of the doctrines essential to Christianity while retaining many of their own diverse rituals and liturgies. Through his programme of learned ignorance, he envisions the possibility of worshipping a God who, as infinite, is neither trine nor one in any sense in which trineness and oneness are positively conceivable by us. By thus adapting Eckhart's distinction between God and Godhead, Nicholas can regard the doctrine of the Trinity as no longer a stumbling block to Jews and Muslims.

9 Conclusion

Nicholas' system of thought is often misapprehended, sometimes in a way that detracts from his real genius, sometimes in a way that is all too flattering of his intellectual accomplishments. A proper grasp of his ideas will locate him, no doubt, somewhere between the invective of John Wenck, who condemns him as a corrupter of Aristotelianism, and the praise of Heinrich Rombach, who sees him as a new Aristotle for the modern period, as someone whose anti-substantive, functionalist ontology is as revolutionary as was Aristotle's introduction of hylomorphism in the first place.

JASPER HOPKINS

List of works

1 Major Latin editions

Nicholas of Cusa (1433-64) *Collected Works*, Strasbourg: Martin Flach, 1488. (Based upon codices Latini Cusani 218 and 219. Newly reprinted as *Werke*, ed. Paul Wilpert, Berlin: Walter de Gruyter, 1967, 2 vols.)

Nicholas of Cusa (1433-64) *Collected Works*, Paris: Jacques Le Fèvre d'Etaples, 1514; repr. Frankfurt: Minerva, 1962.(Adds to the Strasbourg edition *De concordantia catholica*, *De deo abscondito*, *Coniectura de ultimis diebus*, certain mathematical *opuscula* and excerpts from the *Sermones*. Contains many editorial emendations. The later Basel edition of 1565 follows the wording of the Paris edition but adds several mathematical works; like previous editions, it lacks *De li non aliud*.)

Nicholas of Cusa (1433-64) *Collected Works*, Heidelberg Academy of Letters edition, Leipzig/Hamburg: Meiner, 1932-.(Series remains in progress. The most reliable of the editions.)

Nicholas of Cusa (1445-59) *Mathematical Writings*, trans. J. Hofmann, *Die mathematischen Schriften*, Hamburg: Meiner, 2nd edn, 1979.(A German translation of the mathematical works, together with an introduction, extensive notes and important manuscript information.)

2 Individual works

Nicholas of Cusa (1433) *Opusculum contra Bohemorum errorem: De usu communionis (A Short Work Against the Error of the Hussites: On the Celebration of Communion)*, in the Paris edition of *Collected Works*, vol. II, 2, ff. 5^{r}-13^{v}.(This is a single work, though the Paris edition divides it into two works.)

Nicholas of Cusa (1433) *De maioritate auctoritatis sacrorum conciliorum supra auctoritatem papae (On the Superiority of the Authority of the Sacred Councils to the Authority of the Pope)*, text ed. E. Meuthen, printed in Abhandlungen der Heidelberger Akademie der Wissenschaften, Philosophisch-historische Klasse, 1977, Abhandlung 3.(One of Nicholas' early works, on papal authority.)

Nicholas of Cusa (1433) *De concordantia catholica (The Catholic Concordance)*, trans. P. Sigmund, Cambridge: Cambridge University Press, 1991.(On the demarcation of papal authority.)

Nicholas of Cusa (1433) *Libellus inquisitionis veri et boni (A Short Book Investigating the True and the Good).* (No longer extant.)

Nicholas of Cusa (1433 or 1434) *De modo vero habilitandi ingenium ad discursum in dubiis (On the Correct Manner of Training the Mind for Reasoning about Doubtful Matters)*.(No longer extant.)

Nicholas of Cusa (1434) *De auctoritate praesidendi in concilio generali (On Presidential Authority in a General Council)*, trans. H.L. Bond *et al.*, *Church History* 59, 1990: 19-34.(On the demarcation of papal authority.)

Nicholas of Cusa (1436) *De reparatione kalendarii (On Amending the Calendar)*, text ed. V. Stegemann, in *Die Kalenderverbesserung. De correctione kalendarii*, Schriften des Nikolaus von Cues, Heidelberg: Kerle, 1955. (Nicholas' proposals for reforming the calendar.)

Nicholas of Cusa (1440) *De docta ignorantia (On Learned Ignorance)*, trans. J. Hopkins, *Nicholas of Cusa on Learned Ignorance*, Minneapolis, MN: Banning, 1985.(Nicholas' best-known work, setting out his doctrine of 'learned ignorance'.)

Nicholas of Cusa (1441-2) *De coniecturis (On Surmises)*, trans. W.F. Wertz, *Toward a New Council of Florence*, Washington, DC: Schiller Institute, 1993.(Recent translation.)

Nicholas of Cusa (1444 or earlier) *De Deo abscondito (On the Hidden God)*, trans. J. Hopkins, *A Miscellany on Nicholas of Cusa*, Minneapolis, MN: Banning, 1994.(Recent translation.)

Nicholas of Cusa (1445) *De quaerendo Deum (On Seeking God)*, trans. J. Hopkins, *A Miscellany on Nicholas of Cusa*, Minneapolis, MN: Banning, 1994.(Recent translation.)

Nicholas of Cusa (1445) *De filiatione Dei (On Being a Son of God)*, trans. J. Hopkins, *A Miscellany on Nicholas of Cusa*, Minneapolis, MN: Banning, 1994. (In Book 3, Nicholas likens all created beings to mirrors.)

Nicholas of Cusa (1445) *De geometricis transmutationibus (On Geometrical Transformations)*, in the Paris edition of *Collected Works*, vol. II, 2, ff. 33^{r}-53^{v}.(Edition of mathematical work.)

Nicholas of Cusa (1445) *De arithmeticis complementis (On Arithmetical Complements)*, in the Paris edition of *Collected Works*, vol. II, 2, ff. 54^{r}-58^{v}.(Edition of mathematical work.)

Nicholas of Cusa (1445-6) *De dato patris luminum (The Gift of the Father of Lights)*, trans. J. Hopkins, *Nicholas of Cusa's Metaphysic of Contraction*, Minneapolis, MN: Banning, 1983. (Recent translation.)

Nicholas of Cusa (1446) *Coniectura de ultimis diebus (A Surmise Regarding the Last Days)*, in the Heidelberg Academy edition of *Collected Works*, vol. IV, *Opuscula*. (Reliable edition.)

Nicholas of Cusa (1447) *Dialogus de genesi (On the Genesis [of All Things])*, trans. J. Hopkins, *A Miscellany on Nicholas of Cusa*, Minneapolis, MN: Banning, 1994.(Nicholas' writings on creation.)

Niebuhr, Helmut Richard (1894-1962)

After early writings interpreting the social dimensions of US religious life from a Protestant point of view, Helmut Richard Niebuhr came increasingly to focus on theology, the interpretation of the Word and experience of God, and ethics, the attempt to live a responsible life grounded in the deepest values. More successfully than any contemporary, he brought into creative tension two major strands of modern Christian thought. From the liberal tradition, he came to stress the relativity of all statements about God and accented the situation of the believer who makes them. Niebuhr matched or countered this perspectival approach with an inheritance from 'neo-orthodoxy' which stressed the otherness of God, the distance between God and all human experiences, statements and perspectives. While preoccupied with witness to 'God beyond the gods', Niebuhr was also devoted to understanding the human in the light of the experience of God. He developed comprehensive views of the responsible self as the focus of ethics and emphasized the communal dimensions of human life.

1 The sovereignty of God

Helmut Richard Niebuhr was born in Wright City, Missouri, on 3 September 1894. He acquired theological interests early as the son of a well-read small-town pastor; his brother, Reinhold Niebuhr, also became a prominent theologian. The sermons he heard as a child reflected German Protestant traditions, which were nurtured in the college and seminary life of the Evangelical and Reformed tradition. After receiving a PhD at Yale in 1924 and studying at Berlin and Marburg in 1930, he taught at Yale Divinity School (adjacent to a secular university), where seminarians from many denominations studied. His thought was never devoted to sectarian interests, but reflected and kept in mind the ecumenical context, and addressed the world of those who cared little for the Christian faith. He died on 5 July 1962.

Despite the broadness of Niebuhr's thought, many of its accents are developments of the Reformed background. In the tradition associated with John Calvin (§3), he witnessed to a God who is not the product of human imagination, not one among many deities, not merely immanent and able to be taken captive within human affairs, and not capable of compromising or being compromised. This is the 'God beyond the gods', not to be confused with the idols and deities manufactured by humans to justify their nations, Churches or other institutions. The ethical human being is to draw their values from reference to this sovereign God.

Niebuhr balanced this view of God, which in philosophical terms he called 'radical monotheism', with a very realistic view of the way human beings grasped the activity of God. God is indeed active in the world in a distinctive way through Jesus Christ; he is testified to in the Bible, engaged in human affairs through the life of the Church and manifestly holds humans responsible for actions that could be valued as good.

2 Social history and the kingdom of God

Not a biblical scholar, Niebuhr was frankly a philosophical theologian at a time when American Protestant elites often denigrated philosophy. He was not so much a precise or seminal philosophical thinker as someone who carried on a lifelong dialogue with philosophers, at first with social and political thinkers. This led him to write a sociological and then a historical interpretation of modern and especially American religious life. In *The Social Sources of Denominationalism* (1929), he displayed an almost deterministic view of what social class did to shape Churchly response. At that time he was strongly influenced by the German social philosopher Ernst Troeltsch, who led Niebuhr towards relativism, or at least towards the need to see the relativity of all human witness to God. He later wrote his own critique of this sociological determinism, *The Kingdom of God in America* (1937). In it, he accented the way the experience of God and thinking about God shaped the life of the American nation.

A third historical work, *Christ and Culture* (1951), saw him move towards a classifying system for relating the believing community to the culture around it. He tended to favour two views: 'Christ Transforming Culture', in which responsible humans in community set out to realize something of the coming kingdom of God; and 'Christ and Culture in Paradox', a dialectical view which showed Christians at times affirming and at times negating the main elements of culture. These reflect Niebuhr's own view of the limits of human achievement, and his belief in the need to be responsible within culture.

3 Theology and Jesus Christ

While writing these three more or less historical works, Niebuhr came to favour a more abstract and philosophical approach to theology. Through it all, he kept two poles of thought in the front of his mind. One was witnessed to in *Radical Monotheism and Western Culture* (1960), a judgment upon all efforts to reduce God to a cultural artefact or to claim God for favoured human causes. His last book, *The Responsible Self* (published posthumously in 1963), demonstrated that he had never left behind his preoccupation with conscience, community and responsibility. He died before being able to complete a synthetic work. Yet his life and teachings were sufficiently consistent for one to be able to deduce the elements of a complete systematic theology. Two generations of Niebuhr students went from Yale to strategic positions in theological schools, there to develop these poles of his thought.

As a Christian philosophical theologian, Niebuhr naturally focused on the figure of Jesus Christ. He connected Jesus chiefly with the redeeming activity of God. Niebuhr spent little time revisiting ancient creedal categories, largely shaped under Greek influence, in order to deal with the ways the human Jesus is to be regarded as a distinctive expression of divine action. He chose historical more than philosophical language for this purpose. Jesus was first of all a pious Jew, a person of his times. He was a proclaimer of the sovereignty of God, of radical monotheism focused on the one he called 'Father'. He was also a mediator of faith, who proclaimed and brought about for human beings a new relation to God.

4 Theory of value and the responsible self

Rather than make original contributions to what Christians call Christology, Niebuhr related Jesus to Niebuhrian theories of values and valuation. Jesus embodied the revelation of God and used his situation to offer a new covenant with God, a revolutionary impulse that called others who saw him as an exemplar of faith to change the world around them. One of Niebuhr's students, Hans Frei, summarized well the way Niebuhr could speak of 'the teaching and acts of Jesus Christ, his moral virtues' as offering 'the direct clue to his being'. In these, one may find 'in faith, hope and love, the unique moral Sonship to God of one who is completely at one with men' (Frei 1957: 115).

Niebuhr is usually described as a confessional theologian, that is, a thinker about God who interprets the 'confessions' or creeds of the believing community. In fact, he presented two perspectives. One is indeed 'internal', the 'we' language of the community. But there is also the perspective of the sociologist, historian or analyst, who looks at the community from the 'external' point of view and sees a very different sort of reality. It is this understanding that has led Niebuhr to be described, second, as a 'perspectival' thinker - not a mere relativist, but someone acutely conscious of the relativity of all human experience and discourse, the perspectives through which people interpret God's action.

On the basis of these interpretations, Niebuhr can be seen, third, as a philosophical theologian of 'value'. For him, the experience of God and the witness to God are not ends in themselves, having no connection with action in the public world. On the contrary, the witness to God should impel responsible selves to give expression to that which they value. God is the source and centre of value, and knowledge of God leads believers to patterns of loyalty that help them to develop appropriate scales of value with respect to the things of the world. For the believer, knowing is a matter that involves valuing. The act of valuing is not capricious, not a matter of mere preference, but is related to the deepest commitments of life. Being and value are inseparable in Niebuhr's thinking. While this could have meant 'Whatever is, is right', for Niebuhr it had to be 'Whatever is, is good', since 'Being' for him meant the Being of the creator God who is good and creates good. The person of faith becomes the one who knows, in a limited way at least, to trust Being, God, the source and centre of values. This view of values and valuation relates again to Niebuhr's lifelong interest in the God who holds human beings responsible, and in human beings who, for all their limits, should be responsive to God; this means that they should be bound in loyalty to the signals of the 'Creative Action of God', the 'Governing Action of God', and the 'Redemptive Action of God'.

Philosophers interested in thinkers who would prove the existence of God and describe the divine attributes would be frustrated upon encountering Niebuhr, who never tried to do either. In *The Meaning of Revelation* (1941), another major work, he describes the experience and confession of a revealing God who, in the ambiguities of history, summons people to trust and to responsible action. Niebuhr elaborated this perspective of the believing community and its 'internal' history as well as anyone in American Protestantism in his time, and remained a

consistent witness to radical monotheism.

Niebuhr, Reinhold (1892-1971)

Reinhold Niebuhr is widely regarded as the foremost public theologian in twentieth-century America. A 'public' theologian is one who is responsive to the biblical tradition and responsible to the Christian Church, but who also responds to the social and political concerns of the world and seeks to effect change in that world. In the case of Niebuhr, this meant being attuned to life in the USA as it passed through times of prosperity, depression, war, cold war and cultural complacency. It also meant that he had to be as alert to the secular philosophy and expression of the times as to the biblical and creedal traditions of the Church, and he managed to correlate and connect these in ever-changing ways.

Niebuhr is known as a developer of a school of thought often called 'Christian realism'. Though shaped first by the more optimistic liberal thought of his teachers' generation, which stressed the immanence of God and the potential for goodness in human beings, Niebuhr came to witness to the otherness of God and the drastic limits of human potential. He even helped resurrect the term 'original sin' to describe the human condition, well aware that the term was scorned by most philosophers of his time. Yet over the decades, his realism came to be seen as so appropriate to descriptions of human actions, especially in situations of power, that he attracted a following far beyond Church communities. Niebuhr thus influenced both domestic and international policies. He was seen both as a self-critical theologian who uttered judgments on the Christian Church and the American nation, and as a theologian of the Cold War who issued devastating critiques of Soviet Communism. In the time before the Second World War, when most of the more notable Protestant clerics leaned towards pacifism, Niebuhr let his realistic vision and his opposition to totalitarian powers lead him to argue for 'preparedness' for war and to scold those who refused to see with him a need for military response to the threat of dictators.

1 A theology informed by public life

Reinhold Niebuhr, brother of the equally notable theologian H. Richard Niebuhr, was born in Wright City, Missouri, on 21 June 1892 and died in Stockbridge, Massachusetts, on 1 June 1971. He first learned Reformed Protestant theology from his German-born father, a small-town pastor. Schooled in the rather provincial sphere of his denomination's college and seminary, he moved on to Yale Divinity School and University and from there to a thirteen-year pastorate in industrial Detroit. His next move was to the interdenominational Union Theological Seminary in New York, where he taught from 1930 to 1960. During all these years, he expressed himself through thousands of editorials and articles in religious and secular publications alike, plunged actively into politics, and lectured and preached widely.

At the same time, Niebuhr kept schooling himself in theology and philosophy, though he made no secret of his limits as a philosopher or his lack of interest in its more abstract formulations. However, he was sufficiently disciplined and prestigious as a philosophical theologian to be invited to give the Gifford Lectures at the University of Edinburgh in 1939; these were published as his most systematic work, *The Nature and Destiny of Man* (1941, 1943). Yet for all the philosophical power and passion displayed in that work, Niebuhr came to be more noticed for his comments on the USA and world affairs. He made his mark with a contentious work published at the beginning of the Depression, *Moral Man and Immoral Society* (1932), a book that seemed to be intended to insult liberal theologians. For several years afterwards he was avowedly informed by Marxian critical ideas, though he never advocated radical socialist or communist programmes and soon passed critical judgment on those ideas as well. He developed his reasoned perspective on domestic and international affairs at mid-century in *The Irony of American History* (1952). Although hampered by the effects of a stroke, he continued to comment on the Cold War scene and on American culture for more than a decade after he could no longer teach.

2 The witness to God

The term 'theology' etymologically combines witness (*logos*) with God (*theos*). Theologians thus try to interpret the life of believing communities and the world around them not only in the light of experience, but also with reference to a transcendent God. Niebuhr conformed to this model, since his whole career was devoted to seeing public life, including that of the Churches, in the light of divine activity. His choice to be a theologian of the engaged sort showed an understanding of his own personality, talents and interests, but was also a sign of his limitations. He spent little or no energy on some classic philosophical themes such as the proofs for the existence

of God.

Instead, Niebuhr's God was the God witnessed to in the Hebrew Scriptures and the New Testament, the Bible of the Christian world. Uncommonly informed by Jewish thought at a time when many Christians went their separate way, Niebuhr had identified with rabbis in Detroit who shared his concern for social justice. With them, he explored the tradition of the Hebrew prophets, who, also using the transcendent reference to God to judge human affairs, usually put more energy into confronting their rulers and the religious powers around them than their enemies. Niebuhr's God was therefore the God of the prophets, the one who measures human affairs and finds them wanting.

In *The Irony of American History*, Niebuhr defined the relation of God to human power and potential as succinctly as he did anywhere. It was a self-consciously ironic - as opposed to tragic, comic or pathetic - understanding. He liked to quote Psalm 2: 4, in which the transcendent God is pictured as laughing at and even holding in derision earthly rulers and powers when they are over-proud and unmindful of their limits. At the same time, according to Niebuhr, this God was not witnessed to as being above human affairs or eager to demean and annihilate people. Instead, this God honoured human aspirations and held people responsible.

Niebuhr was often criticized for refusing to do basic theological work. He shunned concepts associated with ontology, metaphysics and epistemology, took much for granted and spent his energies witnessing to the God revealed in the Bible. He was also criticized for not having developed a sustained and sophisticated hermeneutic. There was an often-expressed American pragmatic bent to his use of the Bible. Thus Niebuhr argued that one is drawn to the Bible in human affairs because it seems to represent the most accurate and appropriate description of human nature and the mortal plight. It was a profoundly relevant address to the world he and the realists around him perceived.

Niebuhr's God was active in creating the world and sustaining it, and in judging human pride and pretension. But the same God was also present in history through revelation in Jesus Christ. Again, Niebuhr avoided agendas common among theologians in that he spent little time expounding the natures of the divine and the human in Jesus. He focused on Jesus' ethical proclamation, which he saw to be severe, 'an impossible possibility'. And he saw in the figure of Jesus crucified not only a love that redeemed humans, but also a sign of the evil of a world that could not be just and did not welcome love. So he could say to the 'atheists for Niebuhr', as some of the people who did not share his theology but identified with his social and political outlook (such as Arthur Schlesinger and Hans Morgenthau) waggishly called themselves, that for a full understanding of him and his thought they had to know that he preached Christ crucified, Jesus on the cross.

3 The nature of the human

While God can only be witnessed to, humans are accessible to social scientists, ordinary people making observations, and theologians who use divine perspectives to study them. It was on these grounds that Niebuhr suggested that 'original sin' was the only empirically observable Christian doctrine. However, after disagreements with philosophers such as John Dewey, who wanted to dismiss Niebuhr as a grouchy preacher of doom, he expressed regret for having retrieved the notion, or at least for having chosen the term 'original sin'. He did not want it to suggest how morally low humans could sink, or to shift responsibility from them to someone else (such as Adam in the Genesis myth). Instead, it was intended to signal that all humans have limits that cause them to express their pride and to rebel against God (see Feminist theology §1). These limits were never fully explained; the question as to where evil comes from was of the sort that Niebuhr preferred to hand over to the philosophers, though expecting little yield from their answers. Instead, Niebuhr insisted, the limits are simply 'there' and have to be reckoned with. And though all that humans do is tainted, their evil inclinations and pride do not leave them free to be irresponsible.

If human nature is marked by the sin of pride, the evil effects are most noted in collective life; hence the title of Niebuhr's *Moral Man and Immoral Society*. Less concerned with petty vice or personal errancy than with public life - he believed redemptive love to be at its most effective in more intimate spheres - Niebuhr asked what the particular evils are to which Churches, corporations, political parties and especially nations are prone. He saw little possibility of large-scale self-purification by societies and this led him to stress justice more than love in collective life. Societies have a way of turning even their good intentions into proud and self-interested purposes. For this

reason, Niebuhr came to believe in balances of power, of checking the set of interests of one group by countering them with those of another. It was this pragmatic realism, with its blunt readiness to use power, that so offended Christian and other pacifists who opposed Niebuhr.

4 Christian realism

To those philosophical and cultural critics who thought Niebuhr simply wrong in his assessment of human nature and strategically misguided because his pessimism could lead to passivity, the adjective 'Christian' could be interpreted in either of two ways. To some it was the key to explaining why Niebuhr had gone wrong. The Bible, from which he drew so many ideas, saw human nature against a cosmic and mythic backdrop in which God warred against Satan, heaven was opposed to hell, and humans were utterly evil unless rescued by Christ; anyone bringing such a view to ordinary human affairs would inevitably distort them. On the other hand, fellow Christians often complained that Niebuhr did not do justice to the themes of redemption, love and peace. The central figure of the Christian faith, Jesus of Nazareth, represented and taught the way of peace and was an exemplar of love. In traditional creedal terms, Jesus Christ, as the divine Son of God, effected redemption and helped people begin to realize a new age, a new ordering of being. Why, these critics asked, did Niebuhr so often act and teach as if none of this had happened? Was not his Christianity mere realism, indeed, pessimism?

In the face of such criticisms Niebuhr spent many hundreds of pages pointing to what he thought were the specific Christian dimensions of his philosophy and action. Yes, he would be a realist, not hiding from view the excessively proud antisocial aspects of humans, especially in their collective actions. No, no efforts to educate or reform would bring people to a situation where they could live in an era of progress or move towards Utopia. But the word 'Christian' did signal a different interpretation of realism. Niebuhr liked to think in polar terms, and just as he set redemption against sin, and the kingdom of God against human striving, so he introduced a kind of idealistic note to counter ordinary realism. This ideal was not some abstract or remote notion. It had been present in the utterances of the prophets and embodied and proclaimed by Jesus, who presented humans with something of God's love and therefore of God's very nature. So Niebuhr could praise *agapē*, the Greek New Testament's name for the spontaneous, unmotivated, generous and even reckless love of God, who showed concern for humans even in their waywardness and who made it possible for them to express such love.

The presence of *agapē*, even if one cannot expect to see much of it in the spheres of human self-interest, is realized just often enough in personal affairs to inspire idealistic action in public ones. The ethical teachings of Jesus in the Gospels, for instance, expressed such idealism in the form of love. Niebuhr succinctly addressed the polarity between ideal and reality by observing that if realists are not idealists they are 'inclined to obscure the residual moral and social sense even in the most self-regarding men and nations'; on the other hand, idealists who are not realists 'are inclined to obscure the residual individual and collective self-regard either in the "saved" or in the rational individuals and groups' (1965: 31-2).

Niebuhr was criticized by many orthodox Christians for not revisiting classic ways of discussing the divine nature of Jesus Christ or the metaphysical aspects of the divine-human transaction in the death of Jesus on the cross. Other Christians accused him of drawing too severe a line between the potential for sacrificial love in personal life (a love transcending mere self-interest) and the self-interest that realists saw as marking human affairs so much that the love of Christ could hardly enter political and international transactions. But it is always the hazard of a dialectical thinker who tries to do justice to two contrasting, if not overtly contradictory, poles to be vulnerable from both sides. Niebuhr took this chance, for his worldview was so decisively shaped by such poles as 'idealism' and 'realism', and 'self-interest' and 'sacrificial love' that he could not have avoided dealing with them. In a lifelong devotion to this vision, applied to countless changing situations, Niebuhr left a stamp on American political and Church life deeper than that of any other religious thinker of his times.

Nietzsche: impact on Russian thought

Nietzsche's thought had a massive influence on Russian literature and the arts, religious philosophy and political culture. His popularizers were writers, artists and political radicals who read his works through the prism of their own culture, highlighting the moral, psychological and mythopoetic aspects of his thought and their sociopolitical implications, and appropriating them for their own agendas. Literature addressed to a mass readership disseminated crude notions of a master morality and an amoral Superman.

Russians discovered Nietzsche in the early 1890s. His admirers regarded him as a proponent of self-fulfilment and an enemy of the ''slave morality' of Christianity. Two of them, Dmitri Merezhkovskii (1865-1941) and Maksim Gor'kii (real name Aleksei Peshkov, 1868-1936), were the progenitors of the two main streams of Nietzsche appropriation - the religious and the secular. Merezhkovskii was the initiator of Russian Symbolism. In 1896 he began trying to reconcile Nietzsche and Christianity; this attempt led him to propound an apocalyptic Christianity in 1900 and to found the Religious-Philosophical Society of St Petersburg (1901-3, 1906-17). Its members, the so-called God-seekers, included artists and intellectuals who were also attracted to Nietzsche. As for Gor'kii, his early short stories featured vagrant protagonists who personified crude versions of the slave and the master morality. In 1895 Gor'kii began to dream of a Russian Superman who would lead the masses in a struggle for liberation and imbue them with respect for Man, which he always wrote with a capital letter. During the Revolution of 1905, he and Anatolii Lunacharskii (1875-1933), a Bolshevik admirer of Nietzsche, constructed a Marxist surrogate religion to inspire heroism and self-sacrifice. They believed, as did most Symbolists and some philosophers, that art could transform human consciousness.

New literary schools emerged after 1909. The Futurists exaggerated Nietzsche's anti-rationalism, anti-historicism and cultural iconoclasm. The Acmeists propounded a non-tragic Apollonian Christianity and idealized classical antiquity and 'world culture'. After the Bolshevik Revolution, Nietzsche was considered an ideologue of reaction and his books were removed from the People's Libraries, but his ideas, not identified as such, continued to circulate and pervaded Soviet literature, the arts and political culture.

1 Symbolists

In Russia, literature and literary criticism were the venues for discussing social and political ideas in coded Aesopian language. This applied to Nietzsche as well. Successive generations of writers and critics developed their own interpretations of Nietzsche, polemicizing with their contemporaries and with preceding generations, and basing their arguments on different Nietzsche texts or on variant readings of the same text. Strictly speaking, Nietzsche had no Russian disciples. Rather, his ideas fructified various literary and artistic schools, religious philosophy and Bolshevik political culture. The early twentieth-century religious renaissance was in large part a response to Nietzsche, as was the Soviet obsession with creating a new culture and a new man (*chelovek*); the word is gender neutral but discussions focused on men.

For the Symbolists, the key Nietzsche text was *The Birth of Tragedy*. They were dazzled by Nietzsche's aesthetic justification of the world and human existence, his celebration of the Dionysian, and his belief that myth is essential to the health of a culture. Much of their imagery and their perception of Nietzsche as a mystic and a prophet, derived from *Thus Spoke Zarathustra*.

The first generation of Russian Symbolists - Merezhkovskii, his wife Zinaida Hippius (1869-1945), Konstantin Balmont (1867-1942), Valerii Briusov (1873-1924), N.M. Minskii (N.M. Vilenkin, 1855-1937) and their allies, the modernists of *Severnyi vestnik* (Northern Herald, 1885-98) and the aesthetes of *Mir iskusstva* (The World of Art, 1898-1904) - discovered Nietzsche at a time when the appeal of populism, the surrogate religion of the intelligentsia, was fading. Nietzsche's aestheticism helped fill the spiritual gap. Art became their religion. They saw themselves as warriors for culture and against arid rationalism and emotional repression, as creators who smashed the old 'tables of values' and inscribed their own values on new tables. Balmont regarded the artist as Superman. Later on, Merezhkovskii referred to the Symbolists of the 1890s, including himself, as Decadents.

In a famous 1892 essay on the causes of the decline of Russian literature, Merezhkovskii attacked positivism and populism for debasing and despiritualizing art and argued that Symbolism would lead to new truths (note the

plural) that would unite the atheistic intelligentsia and the Christian people (*narod*). Unlike Nietzsche, most Russian Symbolists believed that higher truths did exist somewhere beyond the Dionysian flux. Only two years later, Merezhkovskii propounded an aesthetic individualism in which self-expression and the creation of beauty were the highest values. In essays and poems, and in his historical novel *Otverzhennyi (The Outcast)* (1895) later published as *Smert' bogov: Iulian Otstupnik (Death of the Gods: Julian the Apostate)*, about the Roman Emperor who tried to restore paganism, he celebrated the liberation of the passions and instincts repressed by Christianity, sexuality in particular, and the Nietzschean theme of laughter. But Merezhkovskii's inordinate fear of death, together with other factors such as his discovery of the cruelty of Roman civilization, led him to reconsider Christianity. In 'Pushkin' (1896), he declared that Christianity articulated the 'truth of heaven' (love and personal immortality) and paganism (really Nietzscheanism), the 'truth of the earth' (enjoyment of worldly pleasures) - two truths that must be reconciled by an all-encompassing higher truth. Asserting that Pushkin had reconciled them unconsciously, Merezhkovskii set about trying to find Pushkin's 'secret'. In the same essay, he also stated that Pushkin was the perfect combination of Apollo and Dionysus, in other words, a Superman in the popular conception of the term. Nietzsche himself expected the Superman to emerge only in the remote Future. Merezhkovskii's essay stimulated new readings of Pushkin well into the Soviet period.

Merezhkovskii's equally seminal book *Tolstoi i Dostoevskii* (1900-2) compared the Russian writers with one another and with Nietzsche. This book was Merezhkovskii's response to Nietzsche's critique of Christianity, which Merezhkovskii now claimed applied only to 'historical Christianity' (Christianity as preached in the churches). A Third Testament or Third Revelation was forthcoming. Jesus Christ himself would show humankind how to reconcile Christianity and paganism. The Revolution of 1905 politicized Merezhkovskii. He regarded it as the beginning of the apocalypse and labelled the Autocracy, the Orthodox Church and middle-class philistinism (*meshchanstvo*) guises of the Beast. Nietzschean elitism helped this Russian aristocrat justify his contempt for the middle class. Like his fellow Symbolists, Merezhkovskii considered Nietzsche an anarchist.

A second generation of Symbolists - Viacheslav Ivanov (1866-1949), Andrei Belyi (1880-1934) and Aleksandr Blok (1880-1921) - emerged after 1900. Ivanov maintained, in 'Ėllinskaia religiia stradaiiushchego Boga' (The Hellenic Religion of the Suffering God) (1904), that Dionysianism was an aesthetic-psychological-religious phenomenon, and that Dionysus was a precursor of Christ. In subsequent essays, Ivanov renounced 'Nietzschean' individualism and the Superman ideal and urged the Symbolists become myth-creators - to articulate the myths around which Russians could unite and thereby end social conflict. During the Revolution of 1905, Ivanov supported a doctrine called Mystical Anarchism, the brainchild of Georgii Chulkov, an anarchist and a former editor of Merezhkovskii's revue *Novyi put'* (New Path, 1902-4). Mystical Anarchism demanded the abolition of all authorities external to the individual - government, law, morality and social custom. Post-apocalyptic society would be characterized by freedom, beauty and love (*eros*, not *agapē*) and would be cemented by passion, myth and sacrifice. These invisible bonds would be forged in a theatre-temple modelled on the Theatre of Dionysus and devoted to myth-creation (*mifotvorchestvo*). The Symbolists would serve as high priests and the spectators would become a chorus and participate actively in the myth-creating process. In the orgiastic ecstasies of the rites, they would shed their separateness and become one, thereby bringing about the communitarian consciousness necessary for a society without coercion. Ivanov's ideas on a Dionysian theatre impressed his contemporaries, and were a major source of the mass festivals and political theatre of the early Soviet period. Ivanov's Christ/Dionysus archetype became a Symbolist trope.

One product of the post-1905 easing of the censorship laws was a vulgar Nietzscheanism (*Nitsheanstvo*) of pornography, nihilism and decadence in literature and in life. Appalled by this phenomenon, Ivanov and Merezhkovskii distanced themselves from Nietzsche. Nevertheless, his ideas continued to shape their thought, informing, for example, the Symbolist concept of life-creation (*zhiznetvorchestvo*) which exalted art as a theurgical activity that would transfigure man and the world. Different Symbolists had their own versions.

Nietzsche's ideas were an important component of a mystical revolutionism that associated the people with Dionysus and the intelligentsia with Apollo and bourgeois civilization. Blok predicted, even welcomed, the destruction of the intelligentsia by the enraged people. He, Belyi and a group called the Scythians perceived the Bolshevik Revolution as the beginning of a 'revolution of the spirit' that would engender a new culture and a new man - an artist (see Russian religious-philosophical renaissance §5).

2 Philosophers

Philosophic debate on Nietzsche was initiated by the respected journal *Voprosy filosofii i psikhologii (Questions of Philosophy and Psychology)* and centred on his critique of Christian morality. In October 1892, the journal published 'Friedrich Nietzsche: The Critique of Altruism' by V.P. Preobrazhenskii (1864-1900) who praised Nietzsche as a moralist, a defender of freedom and an advocate of the elevation and strengthening of the human person. Three articles in the next issue (January 1893) attacked Nietzsche as an amoralist and a decadent. The discussion spilled over into other journals. Nikolai Mikhailovskii (1842-1904), editor of the Populist journal *Russkoe bogatstvo (Russian Wealth)* and a long-time advocate of the efficacy of individual action, regarded Nietzsche as an ally in his struggle against Marxist collectivism and historical determinism, as an advocate of a higher morality. As a socialist, Mikhailovskii recognized and objected to the anti-democratic implications of the Superman ideal. Vladimir Solov'ëv (1853-1900), the most influential philosopher of this period, described Nietzsche's idea of the Superman as 'mangodhood', the obverse of his own idea of *Bogochelovechestvo* (*Godmanhood*). Decrying Nietzsche's separation of beauty and power from religion, Solov'ëv maintained that only religion can free beauty from death. He also argued that even though the Superman ideal was demonic, it was religiously significant because it expressed a desire for human perfection, a yearning to be more than human. The Symbolists combined Solov'ëv and Nietzsche in various ways, in the above-mentioned concept of life-creation for example.

Nietzsche was of central importance to Nikolai Berdiaev (1874-1948), Semën Frank (1877-1950) and Lev Shestov (1866-1938). Nietzsche confirmed and reinforced their objections to positivism and rationalism, and challenged them to think about goodness, truth and beauty in new ways.

In their contribution to the symposium *Problemy idealizma (Problems of Idealism)* (1902), Berdiaev and Frank, two former Marxists turned Neo-Kantians, tried to accommodate Nietzsche to Kant. Berdiaev wanted to replace Kant's 'morality of duty' with a higher Nietzschean morality of free desire, but in the same essay he declared that man had a duty to become a Superman. He regarded the Superman as a religious-metaphysical ideal and envisaged a spiritual aristocracy roughly comparable to Nietzsche's 'new nobility'. Frank interpreted Zarathustra's 'love for the most distant' as love for distant goals such as truth, justice and beauty, as opposed to love for the nearest, for one's neighbour. Frank also talked about a 'new nobility', a spiritual or cultural elite, that struggled to realize its ideals. Years later, Frank credited Nietzsche with revealing to him the reality of the psyche and of spiritual life.

Berdiaev came to consider Nietzsche the forerunner of a new religious anthropology and the unwitting prophet of a new Christianity of freedom ungrounded in material reality, of limitless creativity, unprecedented beauty, and self-overcoming. In *Smysl tvorchestva: opyt opravdanie cheloveka (The Meaning of the Creative Act: An Attempt at the Justification of Man)* (1916), he maintained that the Third Revelation will be about man and will be accomplished in a free creative act. Nietzsche's goal, he said, was 'not to justify creativity by life but to justify life by creativity' ([1916] 1954: 110). At a time when most of his contemporaries had distanced themselves from Nietzsche, Berdiaev lauded *Thus Spoke Zarathustra* as 'the most powerful human book without Grace; whatever is superior to Zarathustra is so by Grace from on high' ([1916] 1954: 90).

Shestov maintained that reason can neither explain nor assuage misfortune, suffering or ugliness. In *Dobro v uchenii gr. Tolstogo i Fr. Nitshe (The Good in the Teaching of Tolstoi and Nietzsche)* (1900) and *Dostoevskii i Nitshe - filosofiia tragedii (Dostoevsky and Nietzsche: The Philosophy of Tragedy)* (1903), he used Nietzsche to negate the 'rational morality' of self-renunciation preached by Kant and Tolstoi, and to argue against rational systems in general. Unlike the philosophers mentioned above, Shestov did not consider Nietzsche an advocate of a higher morality; rather Shestov insisted that Nietzsche was not a moralist at all, for he showed that people must seek God rather than 'the good'. In subsequent works, Shestov attacked philosophical systems that impose a non-existent unity on the world and gloss over the horrors of life. His religious existentialism reminds one of Kierkegaard's, whom he discovered in the late 1920s.

3 Bolsheviks

Nietzsche's most important Bolshevik popularizers - Gor'kii (even though he did not join the Party), Anatolii Lunacharskii and Aleksandr Bogdanov (Aleksandr Malinovskii, 1873-1928) - wanted to restore heroism and voluntarism to Marxism and to supplement Marx's teachings with new findings in the social and the physical

sciences. All of them maintained that under socialism, Kant’s ’morality of duty’ would be superseded by a morality of free desire, a ’master morality’, so to speak, but for everyone. They invoked the power of creative will, emphasized the collective aspects of Dionysianism (self-forgetting) and quoted Zarathustra’s dictum ’man is a bridge and not a goal’. Nietzsche’s powerful future-orientation and his related espousal of instrumental cruelty (as distinct from sadism), were taken up without acknowledgement by the Leninist-Marxists, especially Trotsky.

Nietzsche helped Gor’kii substitute an ethos of self-development for the Populist dictum that the writer must serve the people. Later on, Gor’kii tried to develop a Nietzschean aesthetic for a socially committed literature that promoted reason and science as guides to life. After he allied with the Bolsheviks in 1905, he denounced what he took to be Nietzschean individualism as philistinism. Gor’kii’s favourite Nietzsche text was ’On War and Warriors’ in *Thus Spoke Zarathustra*, which includes the line ‘man is something that must be overcome’. Also important to Gor’kii was Zarathustra’s injunction ’be hard - all creators are hard’. For most of his life, Gor’kii regarded the masses as sources of Dionysian energy, to be channelled by an Apollonian elite.

Lunacharskii discovered Nietzsche in 1901. Nietzsche helped him reconcile his love of the arts with his commitment to revolution. He claimed that art is a powerful stimulus to revolutionary ardour, described the ’will to power’ as the ’will to creativity’ (including social creativity), and called the Marxist ideal of a just and harmonious society an aesthetic ideal.

During the Revolution of 1905, he and Gor’kii developed the Marxist surrogate religion of *Bogostroitel’stvo* (God-building). It extolled the heroic proletariat as saviour of humanity, preached worship of collective humanity, and promised collective immortality to encourage people to risk death fighting for socialism. The basic texts of God-building are Lunacharskii’s *Religiia i sotsializm (Religion and Socialism)* (2 vols, 1908, 1911), Gor’kii’s novel *Ispoved’ (Confession)* (1908) and his essay ’The Destruction of the Person’ (1909), written against individualism. *Confession* includes a scene in which the energies of an assembled crowd raise a paralyzed girl; it also includes a Superwoman, aptly named Christina.

Strictly speaking, Bogdanov was not a God-builder, but he did try to create a new myth. He wrote the utopian novels *Krasnaia zvezda (Red Star)* (1908) and *Inzhener Menni (Engineer Menni)* (1913), about a perfected communist society on the planet Mars, to inspire the workers to continue their struggle by showing them what they were fighting for. Bogdanov’s vision was based on an ultra-collective, ultra-egalitarian interpretation of Marxism which denigrated the individual as a ‘bourgeois fetish’. Paradoxically, Bogdanov claimed that communism would facilitate self-development. He hated authoritarianism and militarism. His ideal world had no experts, no hierarchies and no would-be Supermen. It was a world of proletarian renaissance persons (he was a partisan of gender equality) who had conquered nature or at least kept it at bay. They were guided by ‘expediency norms’ that changed as conditions changed, as distinct from ‘coercive norms’ (absolute commandments) and eternal truths. Bogdanov’s first ‘expediency norm’ was ‘there shall be no herd instinct’.

Bogdanov maintained that the Revolution of 1905 failed because the workers were culturally and psychologically unprepared to assume power. Therefore, he argued, cultural revolution must precede and accompany political revolution. Lenin disagreed. In 1909, he had Bogdanov expelled from the Party. The expulsion gave Bogdanov time to develop his concept of cultural revolution, by which he meant: the psychological and spiritual emancipation of the proletariat from bourgeois dominance, systematic revaluation of the cultural legacy from a proletarian perspective, and the construction of a distinctively proletarian art and science. Bogdanov’s views inspired Proletkult (proletarian culture), an extra-Party movement that he, Lunacharskii and others founded in October 1917. Gor’kii was not among them; he wanted culture to be above class. At its peak in 1921, Proletkult numbered half a million members and had an extensive network of schools, art studios and theatres. The movement collapsed after Lenin attacked it, but crude versions of Bogdanov’s ideas were perpetuated by self-styled proletarian groups during the culture wars of the 1920s, and helped inspire Stalin’s cultural revolution of 1928-31. Gor’kii championed Socialist Realism, the Stalinist form of myth-creation and the official aesthetic of the Soviet Union from 1934, when it was officially adopted by the first Congress of Soviet Writers, until well after Stalin’s death. Lunacharskii was involved in preparatory activities but he died before the Congress met (see Russian empiriocriticism).

4 Futurists and Acmeists

To the Futurists, the key Nietzsche text was the madman’s announcement of the death of God in *The Gay Science* (§125) and the chaotic, directionless, universe and infinite horizons that ensue. Their foundational myth was *Pobeda nad solntsem* (Victory Over the Sun) (1913), the title of an operetta about the capture of the sun (Apollo), which occurs offstage, by Futurist strongmen. These new people are male or androgynous, but definitely not female. They speak a new language - *zaum* - literally ‘beyond the mind’, a concept inspired, in part, by Nietzsche’s attack on ‘reason in language’ and his association of language and power. The Futurists advocated a complete break with history, exaggerating the anti-historicism and celebration of youth in Nietzsche’s *The Advantage and Disadvantage of History for Life*, and they wished to jettison the cultural legacy. The bellicosity of their language and their aggressive masculinism echoed some of Nietzsche’s most ferocious passages. Their unabashed primitivism and orientation to Asiatic Russia stemmed from a literal reading of Nietzsche’s ‘new barbarians’ and indicated their desire to create *de novo*. Paradoxically, they were enthralled by technology, large cities and noisy crowds. *Pobeda nad solntsem* was performed together with *Vladimir Maiakovskii: Tragediia*, by Vladimir Maiakovskii (1893-1930), which was structured like a Dionysian dithyramb and included Maiakovskii’s version of the Christ/Dionysus archetype. Maiakovskii knew *Thus Spoke Zarathustra* well; his pre-Revolutionary poetry is permeated with images and themes drawn from it. Many Futurists were also painters; their alogism was a pictorial counterpart to *zaum*.

The Futurists brought the issues of language and form to the centre of literary debates, where they remained for over two decades. Their cultural iconoclasm and anti-bourgeois stance were easily politicized. After the Bolshevik Revolution they achieved quasi-official status. They maintained that a ’revolution of the spirit’ was needed to complete the political and social revolution and tried to establish their own dictatorship of taste.

The Acmeists, a short-lived group of poets that included Nikolai Gumilëv (1886-1921) and Osip Mandel’shtam (1891-1938), developed the concept of the Apollonian in a way that enabled them to reconcile Hellenism with Orthodox Christianity in a poetic exaltation of earthly reality. Rejecting theurgy and mysticism, their aesthetics emphasized clarity in language, concreteness and a visual orientation. They defended Christian ethical values (Apollo is the ethical deity), moral courage and ‘manly will’. Gumilëv’s warrior pose and conquistador persona stemmed from *Thus Spoke Zarathustra*; also important to him was Nietzsche’s concept of *amor fati*. Mandel’shtam’s statement that ’to remember also means to invent’ encapsulated his own interpretation of Nietzsche’s views on history and myth and affirmed past values and ’world culture’. The Acmeists were persecuted during the Soviet period. Gumilëv was executed for treason; Mandel’shtam died in the Gulag.

5 The Soviet period

Unacknowledged Nietzschean ideas (ideas mediated by Nietzsche’s Russian popularizers) helped shape Soviet literature and culture, including political culture, in ways too numerous and complex to be detailed here. They inspired literary, artistic and architectural experimentation, a ruthless revolutionary morality and cultural construction. In addition, they underlay the Lenin Cult, the Stalin Cult, socialist realism and the grandiose projects of the first and second five-year plans. Nietzschean themes were taken up by now-forgotten poets and playwrights and by such Soviet luminaries as the writer Isaac Babel, the theatrical director Vsevolod Meierhol’d and the film director Sergei Eisenstein. The religious stream of Nietzsche appropriation was perpetuated by Boris Pasternak, Mikhail Bakhtin and other disaffected intellectuals.

Nietzsche’s name was linked with ’isms that the government denounced: bourgeois individualism and nihilism in the 1920s, fascism in the 1930s, and bourgeois hedonism in Brezhnev’s time. The few books and articles about Nietzsche published after 1927 quoted *Beyond Good and Evil* and *The Will to Power* extensively, but his works remained inaccessible to ordinary readers. Under Gorbachev’s policy of *glasnost’* Nietzsche’s writings were reprinted in press runs of 100,000, which sold out immediately.

Editor's introduction includes discussion of methodological problems of assessing a buried influence.)

Nietzsche, Friedrich (1844-1900)

Appointed professor of classical philology at the University of Basel when he was just 24 years old, Nietzsche was expected to secure his reputation as a brilliant young scholar with his first book, Die Geburt der Tragödie (The Birth of Tragedy) (1872). But that book did not look much like a work of classical scholarship. Bereft of footnotes and highly critical of Socrates and modern scholarship, it spoke in rhapsodic tones of ancient orgiastic Dionysian festivals and the rebirth of Dionysian tragedy in the modern world. Classical scholars, whose craft and temperament it had scorned, greeted the book with scathing criticism and hostility; even Nietzsche eventually recognized it as badly written and confused. Yet it remains one of the three most important philosophical treatments of tragedy (along with those of Aristotle and Hegel) and is the soil out of which Nietzsche's later philosophy grew. By 1889, when he suffered a mental and physical collapse that brought his productive life to an end, Nietzsche had produced a series of thirteen books which have left a deep imprint on most areas of Western intellectual and cultural life, establishing him as one of Germany's greatest prose stylists and one of its most important, if controversial, philosophers.

Nietzsche appears to attack almost everything that has been considered sacred: not only Socrates and scholarship, but also God, truth, morality, equality, democracy and most other modern values. He gives a large role to the will to power and he proposes to replace the values he attacks with new values and a new ideal of the human person (the Übermensch *meaning 'overhuman' or 'superhuman'). Although Nazi theoreticians attempted to associate these ideas with their own cause, responsible interpreters agree that Nietzsche despised and unambiguously rejected both German nationalism and anti-Semitism. Little else in his thought is so unambiguous, at least in part because he rarely writes in a straightforward, argumentative style, and because his thought changed radically over the course of his productive life. The latter is especially true of his early criticism of Socrates, science and truth.*

Nietzsche's philosophizing began from a deep sense of dissatisfaction with modern Western culture, which he found superficial and empty in comparison with that of the ancient Greeks. Locating the source of the problem in the fact that modern culture gives priority to science (understood broadly, including all forms of scholarship and theory), whereas Presocratic Greece had given priority to art and myth, he rested his hopes for modern culture on a return to the Greek valuation of art, calling for a recognition of art as 'the highest task and the truly metaphysical activity of this life'.

He soon turned his back on this early critique of science. In the works of his middle period he rejects metaphysical truth but celebrates the valuing of science and empirical truth over myth as a sign of high culture. Although he had earlier considered it destructive of culture, he now committed his own philosophy to a thoroughgoing naturalistic understanding of human beings. He continued to believe that naturalism undermines commitment to values because it destroys myths and illusions, but he now hoped that knowledge would purify human desire and allow human beings to live without preferring or evaluating. In the works of his final period, Nietzsche rejects this aspiration as nihilistic.

In his final period, he combined a commitment to science with a commitment to values by recognizing that naturalism does not undermine all values, but only those endorsed by the major ideal of value we have had so far, the ascetic ideal. This ideal takes the highest human life to be one of self-denial, denial of the natural self, thereby treating natural or earthly existence as devoid of intrinsic value. Nietzsche saw this life-devaluing ideal at work in most Western (and Eastern) religion and philosophy. Values always come into existence in support of some form of life, but they gain the support of ascetic religions and philosophies only if they are given a life-devaluing interpretation. Ascetic priests interpret acts as wrong or 'sinful' because the acts are selfish or 'animal' - because they affirm natural instincts - and ascetic philosophers interpret whatever they value - truth, knowledge, philosophy, virtue - in non-natural terms because they share the assumption that anything truly valuable must have a source outside the world of nature, the world accessible to empirical investigation. Only because Nietzsche still accepted this assumption of the ascetic ideal did naturalism seem to undermine all values.

According to his later thought, the ascetic ideal itself undermines values. First it deprives nature of value by placing the source of value outside nature. Then, by promoting the value of truth above all else, it leads to a denial that there is anything besides nature. Among the casualties of this process are morality and belief in God, as

Nietzsche indicated by proclaiming that 'God is dead' and that morality will gradually perish. Morality is not the only possible form of ethical life, however, but a particular form that has been brought about by the ascetic ideal. That ideal has little life left in it, according to Nietzsche, as does the form of ethical life it brought about. Morality now has little power to inspire human beings to virtue or anything else. There is no longer anything to play the essential role played by the ascetic ideal: to inspire human beings to take on the task of becoming more than they are, thereby inducing them to internalize their will to power against themselves. Modern culture therefore has insufficient defences against eruptions of barbarism, which Nietzsche predicted as a large part of the history of the twentieth and twenty-first centuries.

But Nietzsche now saw that there was no way to go back to earlier values. His hope rested instead with 'new philosophers' who have lived and thought the values of the ascetic ideal through to their end and thereby recognized the need for new values. His own writings are meant to exhibit a new ideal, often by exemplifying old virtues that are given a new, life-affirming interpretation.

1 Life

Nietzsche was born in Rocken, a small village in the Prussian province of Saxony, on 15 October 1844. His father, a Lutheran minister, became seriously ill in 1848 and died in July 1849 of what was diagnosed as 'softening of the brain'. His brother died the following year, and Nietzsche's mother moved with her son and daughter to Naumberg, a town of 15,000 people, where they lived with his father's mother and her two sisters. In 1858, Nietzsche was offered free admission to Pforta, the most famous school in Germany. After graduating in 1864 with a thesis in Latin on the Greek poet Theogonis, he registered at the University of Bonn as a theology student. The following year he transferred to Leipzig where he registered as a philology student and worked under the classical philologist Friedrich Ritschl. The events of his Leipzig years with the most profound and lasting influence on his later work were his discoveries of Schopenhauer's *Die Welt als Wille und Vorstellung (The World as Will and Representation)* and F.A. Lange's *Geschichte des Materialismus (History of Materialism)*, and the beginning of a personal relationship with Richard Wagner (see Schopenhauer, A. §§3-6; Lange, F.A. §2). Nietzsche became Ritschl's star pupil, and on Ritschl's recommendation he was appointed to the Chair of Classical Philology at Basel in 1869 at the age of twenty-four. Leipzig proceeded to confer the doctorate without requiring a dissertation.

Basel's proximity to the Wagner residence at Tribschen allowed Nietzsche to develop a close relationship with Richard and Cosima Wagner. Sharing with the composer a deep love of Schopenhauer and a hope for the revitalization of European culture, he initially idealized Wagner and his music. His first book, *Die Geburt der Tragödie (The Birth of Tragedy)* (1872), used Schopenhauer's philosophy to interpret Greek tragedy and to suggest that Wagner's opera constituted its rebirth and thereby the salvation of modern culture. Torn between philology and philosophy since shortly after his discovery of Schopenhauer, Nietzsche devoted much of his teaching to the texts of ancient Greek and Roman philosophy and hoped that his first book would establish his credentials as a philosopher. Instead, its unorthodox mixture of philosophy and philology merely served to damage his reputation as a philologist.

In 1879, he resigned his chair at Basel because of health problems that had plagued him for years. In the meantime, he had become progressively estranged from Wagner, a process that culminated in the 1878 publication of the first volume of *Menschliches, Allzumenschliches (Human, All Too Human)*, a positivist manifesto that praised science rather than art as indicative of high culture. The ten productive years left to him after his retirement were marked by terrible health problems and a near absence of human companionship. Living alone in Italian and Swiss boarding houses, he wrote ten books, each of which has at least some claim to being a masterpiece. His last seven books mark a high point of German prose style.

In January 1889, Nietzsche collapsed in Turin. He wrote a few lucid and beautiful (although insane) letters during the next few days, and after that nothing of which we can make any sense. Following a brief institutionalization, he lived with his mother and then his sister until his death in Weimar on 25 August 1900.

2 Writings and development

During the sixteen years between his first book and his last productive year, Nietzsche's thinking underwent remarkable development, usually with little notification to his readers. The traditional grouping of his writings into

three major periods is followed here, although there is significant development within each period. In addition to *The Birth of Tragedy* his early work consists of four essays of cultural criticism - on David Strauss, history, Schopenhauer, and Wagner - published separately but linked together as *Unzeitgemäße Betrachtungen (Unfashionable Observations)* (1873-6), plus a number of largely finished essays and fragments that belong to the *Nachlaß* of the period. The most important of the essays are 'Über Wahrheit und Lüge im außermoralischen Sinne' ('On Truth and Lies in a Nonmoral Sense'), 'Homer's Wettkampf' ('Homer's Contest'), and 'Die Philosophie im tragischen Zeitalter der Griechen' ('Philosophy in the Tragic Age of the Greeks').

These early writings sound a note of great dissatisfaction with European (Enlightenment) culture, of which Socrates is taken as the earliest representative and continuing inspiration. At the base of Socratic culture Nietzsche finds the belief that life's highest goal is the theoretical grasp of truth at which science and philosophy aim. Theory's claim to provide truth has been undermined, he thinks, by the doctrine of Kant and Schopenhauer that discursive thought gives access not to things-in-themselves but only to 'appearance' (see Kant, I. §5; Schopenhauer, A. §§2, 4). Nietzsche's suggestion for saving European culture is that art should replace theory as the most valued, the 'truly metaphysical', human activity. At first, his main argument for elevating art is that it is more truthful than theory. But he also suggests a very different argument: that theory is destructive of culture unless it is guided and limited by the needs of life which art serves. In his essay on history, the second argument has largely replaced the first. He argues that when practised as autonomous theory, devoted solely to truth, history destroys the limited and mythical horizons required by life and action. And if we emphasize for another generation the naturalistic understanding of human beings at which Socratic culture has now arrived (for example, the denial of a cardinal distinction between humans and other animals), we will only further our culture's disintegration into chaotic systems of individual and group egoism. Nietzsche suggests that history can be harnessed to serve the needs of life, for instance when it is written to emphasize great lives and other aspects that encourage individuals to set lofty and noble goals for themselves. Such history is as much art as it is theory or science.

Nietzsche turns decisively away from such criticism of pure theory in the writings of his middle period, *Human, All Too Human* (1878-80) and *Morgenröte (Daybreak)* (1881). He here celebrates as a sign of high culture an appreciation of the little truths won by rigorous method, and presents his own philosophy as a form of natural science that serves only truth. He also commits himself to the truth of the naturalism he earlier considered so dangerous: there is no cardinal distinction between humans and other animals; everything about human beings, including their values, can be explained as a development from characteristics found among other animals. At the beginning of this period Nietzsche struggles with how naturalism can be compatible with a commitment to values, for he sees it as exposing and thereby undermining the illusions that are needed in order to find value in life. In *Human*, his hope is that knowledge will gradually purify 'the old motives of violent desire' until one can live 'as in *nature*', without preferring or evaluating, but 'gazing contentedly, as though at a spectacle' (*Human* §34 [*Werke* IV.2: 50]). Nietzsche later has Zarathustra mock this spectator conception of knowledge and life as 'immaculate perception' (*Zarathustra* II: §15 [*Werke* V.1: 152-5]).

Nietzsche's final period begins with *Die Fröhliche Wissenschaft (The Gay Science)* (1882), which replaces the spectator conception with one in which the 'knower' belongs to the dance of existence and is one of its 'masters of ceremony' (*The Gay Science* §54 [*Werke* V.2: 90]). This formulation expresses his new confidence that naturalism, which he often calls 'knowledge', is compatible with commitment to values. In this period, Nietzsche once again celebrates art, criticizes Socrates and denies the autonomy of theory, suggesting to some that he has reverted to the viewpoint of his early period. Evidence is provided throughout this entry for an alternative interpretation: the later Nietzsche does not deny that theory can provide truth, and he remains as committed to the pursuit of truth as he was in his middle period. The difference is that he now recognizes in even the apparently autonomous theory of his middle period a commitment to an ideal that is external to and served by theory, namely, the ascetic ideal. Nietzsche returns to the suggestion of his first book, that theory is not autonomous; however, he now objects not to theory, but only to the ideal that theory has served (see §§6 and 7 of this entry). The works of Nietzsche's final period are largely devoted to uncovering, criticizing and offering an alternative to that ideal.

Gay Science was followed by *Also Sprach Zarathustra (Thus Spoke Zarathustra)* (1883-5), a fictional tale used as a vehicle for Nietzsche's most puzzling and infamous doctrines, including the overhuman (*Übermensch*), will to power and eternal recurrence. He considered this to be the deepest work in the German language and suggested that chairs of philosophy might one day be devoted to its interpretation. Our surest guides to it at present are the

other books of his final period, especially the two that followed it: *Jenseits von Gut und Böse (Beyond Good and Evil)* (1886) and *Zur Genealogie der Moral (On the Genealogy of Morality)* (1887). These masterpieces show Nietzsche at the height of his powers as a thinker, an organizer and an artist of ideas. Yet some prefer his last five books. At the beginning of 1888, Nietzsche published *Der Fall Wagner (The Case of Wagner)* and then composed four short books before the year was out: *Die Götzen-Dämmerung (The Twilight of the Idols)*, an obvious play on Wagner's *Götterdämmerung (Twilight of the Gods)*, puts the finishing touches to his accounts of knowledge and philosophy and offers his final critique of Socrates; *Der Antichrist (The Antichrist)*, a critique of Pauline Christianity, offers a relatively sympathetic portrait of Jesus; and *Ecce Homo*, Nietzsche's own portrait of his life and work under such chapter headings as 'Why I write such good books'. It is easy to hear signs of his impending insanity in the shrill tone and self-promotion that sometimes takes over in these books (although not in the very funny and brilliantly anti-Socratic chapter headings of *Ecce Homo*), and perhaps also in the fall-off in organizational and artistic power from the masterpieces of the previous two years. *Nietzsche Contra Wagner*, which he dated Christmas 1888, leaves a different impression. Nietzsche's shortest and perhaps most beautiful book, it is a compilation of passages from earlier works, with a few small improvements, as if aiming at perfection. He collapsed nine days later.

3 The *Nachlaß*

Nietzsche left behind a large body of unpublished material, his *Nachlaß*, which technically should include *The Antichrist* and *Ecce Homo*, published by his sister in 1895 and 1908 respectively. However, Nietzsche had made arrangements for their publication and prepared a printer's copy of each. For purposes of understanding his philosophy, these are therefore accorded the same status as his earlier works and are not usually considered to be part of his *Nachlaß*. This entry gives a very secondary role to the remainder of Nietzsche's *Nachlaß*, which includes the relatively polished essays written in the early 1870s (mentioned in §2 of this entry). These essays are informative about Nietzsche's early views, and are sometimes also thought to provide a clearer statement of his later views of truth and language than do the works he published. The interpretation of Nietzsche's development offered here supports a very different view: that Nietzsche chose not to publish these essays because he soon progressed beyond them to quite opposed views.

Another issue that divides interpreters concerns the weight to give to the notes of Nietzsche's later years. Many treat them as material he would have published if he had remained productive for longer. But since he might instead have rejected and disposed of much of this material, others advise great caution in its use. Further, we often cannot determine the use Nietzsche had in mind for particular notes even when he wrote them. Nietzsche *composed* his books to lead prepared readers to certain views. The rich context and clues for reading supplied by his books, when they are attended to, provide a check on interpretive licence and a basis for getting at Nietzsche's own thinking that has no parallel in the case of the *Nachlaß* material. This applies to the entire contents of *Der Wille zur Macht (The Will to Power)*, which some have regarded as Nietzsche's magnum opus. Although he did announce it as 'in preparation', there is evidence that he dropped his plans to publish a work of this title; the book we have is actually a compilation of notes from the years 1883-8 selected from his notebooks and arranged in their present form by his sister and editors appointed by her. Such notes may sometimes help in understanding what Nietzsche actually did publish. But it is difficult to justify giving them priority when they suggest views that differ from and are even contrary to those suggested by a careful reading of Nietzsche's books (see §§11-12 of this entry).

4 Truth and metaphysics

In the writings of his early and middle periods, Nietzsche often appears to deny that any of our theories and beliefs are really true. By the end of his final period, he denies only metaphysical truth. The rejection of metaphysics forms the cornerstone of his later philosophy.

What Nietzsche rejects as metaphysics is first and foremost a belief in a second world, a metaphysical or true world. *Human, All Too Human* offers a genealogy of this belief. Receiving their first idea of a second world from dreams, human beings originally share with 'everything organic' a belief in the existence of permanent things (substance) and free will. When reflection dawns and they fail to find evidence of these in the world accessible to empirical methods, they conclude that these methods are faulty, and that the real world is accessible only to non-empirical methods. They thus take the empirical world to be a mere appearance or distortion of a second

world, which is thereby constituted as the true one. Metaphysics is purported knowledge of this non-empirical world. *The Birth of Tragedy* affirms metaphysics in this sense - 'an artists' metaphysics' he later called it - in the suggestion that perception and science confine us to mere appearance, whereas truth is accessible in the special kind of preconceptual experience characteristic of Dionysian art.

Human, All Too Human sets out to undermine metaphysics by showing that knowledge of a non-empirical world is cognitively superfluous. Nietzsche's Enlightenment predecessors had already established the adequacy of empirical methods to explain what goes on in the nonhuman world. However, belief in a metaphysical world persisted because that world is assumed to be necessary to account for the things of the highest value in the human world. Nietzsche sought to explain the origin of this assumption and to undermine it. The assumption was made, he claims, because thinkers were unable to see how things could originate from their opposites: disinterested contemplation from lust, living for others from egoism, rationality from irrationality. They could deny this origination only by positing for 'the more highly valued thing a miraculous source in the very kernel and being of the "thing-in-itself"'. Nietzsche offers a naturalistic account of higher things, which presents them as sublimations of despised things and therefore as 'human, all too human'. Once it is clear that we can explain their origin without positing a metaphysical world, he expects the interest in such a world to die out. We cannot deny the bare possibility of its existence, however, because 'we view all things through the human head and cannot cut this head off; yet the question remains what of the world would still be there if we had cut it off' (*Human* §§1, 9 [*Werke* IV.3: 19, 25]).

Nietzsche later goes a step further and denies the very existence of a metaphysical world. His history of the 'true' world in *Twilight of the Idols* offers a six-stage sketch of how the metaphysical world came to be recognized as a 'fable'. Stage Four corresponds to the position of *Human*: the 'true' world is cognitively superfluous. In Stage Five, its existence is denied. Stage Six adds that without a true world, there is no merely apparent world either: the empirical world originally picked out as 'merely apparent' is the only world there is. Nietzsche thus makes clear that he has moved beyond the assumption that there *might* be a metaphysical world to a positing of the empirical world as the only one. He dismisses the whole idea of a second world as unintelligible. The books after *Beyond Good and Evil* proceed on this assumption: they no longer claim that the empirical world is a mere appearance or, what amounts to the same thing, that empirical truths are illusions or falsifications.

5 Knowledge

The position on knowledge to which Nietzsche is led by his rejection of metaphysics is a combination of empiricism, antipositivism and perspectivism. Claiming in his later works that 'all evidence of truth comes only from the senses', and that we have science 'only to the extent that we have decided to *accept* the testimony of the senses - to the extent to which we sharpen them further, arm them, and think them through', he considers the rest of purported knowledge 'miscarriage and not yet science', or formal science, like pure logic and mathematics (*Beyond Good and Evil* §134 [*Werke* VI.2: 96]; *Twilight* III §3 [*Werke* VI.3: 69-70]). The latter, he now insists, departing from his earlier stand that they falsify reality, make no claim about reality at all. Nietzsche's empiricism amounts to a rejection of any wholesale disparaging of sense experience, an insistence that the only bases for criticizing or correcting particular deliverances of the senses are other sense experiences or theories based on them.

Nietzsche's antipositivism involves a rejection of two aspects associated with some other versions of empiricism. First, he rejects foundationalism. Anticipating many later critics of positivism, he denies that there is any experience that is unmediated by concepts, interpretation or theory. Sense experience, our only evidence of truth, is always already interpreted, and knowledge is therefore interpretation, as opposed to the apprehension of unmediated facts. Nietzsche also avoids the problem of needing an a priori theory to establish his empiricism, which he bases instead on his genealogy of the belief in a metaphysical world (a genealogy that is itself empirical in that it accepts the testimony of the senses) and a diagnosis and working-through of the intellectual confusions that have locked previous philosophers into that belief. Clearing away these confusions (especially pictures of knowledge that set the world's true nature over against its appearances) removes all intellectual basis for considering sense experience in principle problematic, and all intellectual motivation for pursuing a priori knowledge. Philosophers may, however, still have non-intellectual motives for this pursuit (see §6 of this entry). The upshot of Nietzsche's antipositivism is that what counts as knowledge is always revisable in the light of new or improved experience. This reinforces his empiricism, and in no way devalues empirical theories or denies that

they can give us truth.

Nietzsche’s perspectivism is often thought to imply that empirical knowledge offers us ‘only a perspective’ and not truth. But is perspectivism itself only a perspective? If not, it is false; if so, it is not clear why we should accept perspectivism rather than some other perspective. And Nietzsche himself puts forward as truths not only perspectivism, but also many other claims.

We can avoid saddling Nietzsche with these problems by recognizing that, at least in its mature and most important formulation (at *Geneology* III §12 [*Werke* VI.2: 381-3]), perspectivism is a claim about knowledge; it is not a claim about truth, and it does not entail that truth is relative to perspective. Further, ‘perspectives’ are constituted by affects, not beliefs. The point is *not* that knowledge is always from the viewpoint of a particular set of beliefs and that there are always alternative sets that would ground equally good views of an object (see Relativism). Such a view inevitably saddles perspectivism with relativism and problems of self-reference. Nietzsche’s explicit point in describing knowledge as perspectival is to guard against conceiving of knowledge as ‘disinterested contemplation’.

His early essay ‘Truth and Lie’ did use the impossibility of disinterested knowledge to devalue empirical knowledge, arguing that the latter was only a perspective and an illusion. But the point of the *Genealogy*’s claim that there is ‘only a perspective knowing’ is quite the reverse: to guard against using the idea of ‘pure’ knowing to devalue the kind of knowledge we have. The metaphor of perspective sets up disinterested knowing as the equivalent of the recognizably absurd notion of seeing something from nowhere. If the conception of knowledge ruled out by perspectivism really is absurd, however - and Nietzsche insists that it is - then it excludes only a kind of knowledge of which we can make no sense and which we could not really want. This explains why so many find perspectivism obvious and even self-evident; but so interpreted, it does nothing to devalue empirical knowledge.

Why does Nietzsche deny the possibility of disinterested knowledge? That surely does not follow from the impossibility of seeing something from nowhere. His early basis for this denial was Schopenhauer’s doctrine that the intellect originates as servant to the will, but he accepted the same doctrine in later works on the basis of a thoroughgoing Darwinian naturalism. Human cognitive capacities exist because of the evolutionary advantage they confer on the species, and no such advantage is to be found in attending to any and all features of reality. The intellect must be directed to certain features - initially at least, those most relevant to human survival and reproduction. Affect - emotion, feeling, passion, value orientations - turns the mind in a particular direction, focusing its attention on certain features of reality and pushing it to register them as important; knowledge is only acquired when the intellect is so pushed and focused. Nietzsche’s perspectivism is a metaphorical formulation of this naturalistic understanding of knowledge.

Because knowledge is always acquired from the viewpoint of particular interests and values, there are therefore always other affective sets that would focus attention on different aspects of reality. Nietzsche’s use of the metaphor of perspective thus implies that knowledge is limited in the sense that there are always other things to know, but not that perspectives block our access to truth. Affects are our access, the basis of all access to truth. If its perspectival character raises any problems for knowledge, it is only because being locked into a particular perspective can make one unable to appreciate features of reality that are apparent from other perspectives. Nietzsche’s solution is simple: the more affects we know how to bring to bear on a matter, the more complete our knowledge of it will be.

This does not mean that true knowledge requires assuming as many perspectives as possible. Knowledge does not require complete knowledge, and complete knowledge is not Nietzsche’s epistemological ideal. In fact, he suggests that the greatest scholars tend to serve knowledge by immersing themselves deeply and thoroughly in some particular perspective, so much so that they damage themselves as human beings. The situation is different for philosophers because their ultimate responsibility is not knowledge, but values. To undertake the task to which Nietzsche assigns them, they need practice in shifting perspectives. This explains much that is distinctive about his way of writing philosophy: why it involves so much affect and seems so given to extremes of expression. He uses different affective stances - assuming them for a while - in order to show us features of reality that are visible from them. More importantly, by moving from one perspective to another, he attempts to show philosophers the kind of ‘objectivity’ that is required for their task: objectivity understood not as disinterested contemplation, but as a

matter of not being *locked into* any particular valuational perspective, as an ability to move from one affective set to another.

6 Philosophy and the ascetic ideal

According to Nietzsche, philosophy has been understood as an a priori discipline, a deliverance of pure reason. Given his empiricism, what role can he allow philosophy? In *Human, All Too Human* he claims to practise 'historical philosophy' and denies that it can be separated from natural science, suggesting that he counts empirical theories as philosophy if they illuminate topics of traditional philosophical concern. Attention to the more conceptual aspects of such theories might especially count as continuing the philosopher's traditional role (§§8-9 of this entry provide an example).

Further, Nietzsche's thinking on topics of traditional philosophical concern (§§4-5 of this entry) is philosophical in a more traditional sense, to the extent that it deals with conceptual as opposed to empirical matters. Such 'pure' philosophy is a matter of battling the images and pictures that beguile the mind and lead philosophers into thinking that there are purely philosophical questions to be answered concerning knowledge, truth and reality. Philosophy in this sense functions as therapy, and to the extent that Nietzsche practises it, he counts as a forerunner of Wittgenstein (see Wittgenstein, L. §§9-12).

Like Wittgenstein, Nietzsche gives language a major role in generating the problems and confusions of previous philosophy. He sometimes seems to criticize language itself for falsifying reality, holding the subject-predicate structure of Indo-European languages responsible for philosophers' propensity to think that reality itself must consist of ultimate subjects that could never be part of the experienced world: God and the ego, or indivisible atoms of matter. But he would probably say of language what he ultimately says of the senses: only what we make of their testimony introduces error. Language misleads us into traditional philosophy only if we erroneously assume that linguistic structure offers us a blueprint of reality that can be used to challenge the adequacy of empirical theories. This is similar to Wittgenstein's diagnosis that philosophical problems arise when language is taken away from the everyday tasks for which it is suited and expected to play a different game. Nietzsche's philosopher forces language to play the 'game' of affording insight into a non-empirical world.

Unlike Wittgenstein, however, Nietzsche fights the confusions of traditional philosophy to free us not *from* the need to do philosophy, but *for* what he considers the true task of genuine philosophy. And this task is not a matter of offering empirical theories. In his later work, Nietzsche insists that philosophers should not be confused with scholars or scientists, that scholarship and science are only means in the hands of the philosopher. Gradually it has become clear to him, he says, that philosophers' values are the 'real germ' from which their systems grow. While pretending to be concerned only to discover truth, philosophers have actually been wily advocates for prejudices (values) they call 'truths'. They interpret the world in terms of their own values, and then claim that their interpretation, which they present as objective knowledge, gives everyone reason to accept these values - as the Stoics justified their ideal of self-governance on the grounds that nature itself obeys laws, an interpretation they arrived at by projecting their ideal of self-governance onto nature (*Beyond Good and Evil* §§1-9 [*Werke* VI.2: 207-16]).

Because Nietzsche believes that interpretations of the world in terms of values provide something that is as important as truth, he wants the philosophy of the future to preserve this function of traditional philosophy. He does not, however, wish to preserve two aspects of the way in which previous philosophers have gone about this task: the lack of courage evident in their failure to recognize that they were reading values into the world rather than discovering truth, and the particular values they read into the world.

These values, he claims, have been expressions of the ascetic ideal, the ideal that takes the highest human life to be one of self-denial, denial of the natural self. Behind this ideal, which he finds in most major religions, Nietzsche locates the assumption that natural or earthly existence (the only kind he thinks we have) is devoid of intrinsic value, that it has value only as a means to something else that is actually its negation (such as heaven or nirvana). He claims that this life-devaluing ideal infects all the values supported by most religions (although *The Antichrist* retracts this in the case of Buddhism). Having come into existence in support of some form of life, values gain the support of the ascetic priest only if they are given a life-devaluing interpretation. Acts are interpreted as wrong or 'sinful', for instance, on the grounds that they are selfish or animal, that they affirm natural instincts. Traditional

('metaphysical') philosophers are successors to the ascetic priest because they interpret what they value - truth, knowledge, philosophy, virtue - in non-natural terms. In the background of their interpretations Nietzsche spies the assumption of the ascetic ideal: that whatever is truly valuable must have a source outside the world of nature, the world accessible to empirical investigation. What ultimately explains the assumption that philosophy must be a priori, and therefore concerned with a metaphysical world, is philosophers' assumption that nothing as valuable as philosophy or truth could be intimately connected to the senses or to the merely natural existence of human beings.

The philosophy of Nietzsche's early and middle periods can itself be diagnosed as an expression of the ascetic ideal. We can understand his devaluation of human knowledge in 'Truth and Lie' (his claim that human truths are 'illusions') as a response to the recognition that knowledge is rooted in the world of nature and thereby lacks the 'purity' demanded by the ascetic ideal. And we can surmise that he considered Darwinian naturalism dangerous because he saw that it deprives human life of value - if one accepts the ascetic ideal (see Darwin, C.R.). Indeed, when he embraced the truth of naturalism in *Human* (to the extent of accepting philosophy itself as an empirical discipline), he drew the conclusion that follows from the combination of naturalism and the ascetic ideal: that human life is without value. From the viewpoint of Nietzsche's later philosophy, it is hardly surprising that his early philosophy turns out to be another expression of the ascetic ideal. According to his *Genealogy*, the ascetic ideal is the only ideal of any widespread cultural importance human beings have had so far; it has dominated the interpretation and valuation of human life for millennia. To have escaped the ascetic ideal without having to work through its influence on him would have been impossible.

On the other hand, Nietzsche was also fighting the ascetic ideal. Naturalism works against the supernatural interpretation of human life that has been promoted by the ascetic ideal, and as modern science increasingly shows how much of the world can be understood in naturalistic terms, the influence of the ascetic ideal wanes. Or, rather, it goes underground. Nietzsche denies that science and the naturalism it promotes are themselves opposed to the ascetic ideal. The commitment to science is actually the latest and most noble form of the ascetic ideal, based as it is on the Platonic/Christian belief that God is truth, that truth is divine. This amounts to the assumption that truth is more important than anything else (for instance, life, happiness, love, power) an assumption Nietzsche traces to the ascetic ideal's devaluation of our natural impulses. Thus the development of science and naturalism has been promoted by inculcating the discipline of the scientific spirit - the willingness to give up what one would like to believe for the sake of what there is reason to believe - as the heir to the Christian conscience cultivated through confession. This has thereby worked against the exterior of the ascetic ideal, against the satisfaction it has provided - in particular, the sense that this life, and especially its suffering, has a meaning, that it shall be redeemed by another life. But to work against such satisfaction is not to oppose the ascetic ideal; it is simply to require more self-denial.

Nietzsche believes that we need a new ideal, a real alternative to the ascetic ideal. If philosophers are to remain true to the calling of philosophy and not squander their inheritance, they must create new values and not continue merely to codify and structure the value legislations of ascetic priests. To create new values, however, it will be necessary for philosophers to overcome the ascetic faith that truth is more important than anything else, for truth is not sufficient support for any ideal. Although they must therefore overcome the ascetic ideal to create a new one, undertaking this task responsibly requires the training in truthfulness promoted by the ascetic ideal. The overcoming of the ascetic ideal that Nietzsche promotes is thus a self-overcoming.

7 The 'death of God' and nihilism

Nietzsche is perhaps best known for having proclaimed the death of God. He does in fact mention that God is dead, but his fullest and most forceful statement to this effect actually belongs to one of his fictional characters, the madman of *Gay Science* 125 (*Werke* V.2: 158-60). Nietzsche's madman declares not only that God is dead and that churches are now 'tombs and sepulchres of God', but also that we are all God's 'murderers'. Although the madman may accept these statements as literally true, they clearly function as metaphors for Nietzsche. The 'death of God' is a metaphor for a cultural event that he believes has already taken place but which, like the death of a distant star, is not yet visible to normal sight: belief in God has become unbelievable, the Christian idea of God is no longer a living force in Western culture.

Nietzsche views all gods as human creations, reflections of what human beings value. However, pagan gods were constructed from the qualities human beings saw and valued in themselves, whereas the Christian God was given

qualities that were the opposite of what humans perceived in themselves, the opposite of our inescapable animal instincts. Our natural being could then be reinterpreted as ‘guilt before God’ and taken to indicate our unworthiness. Constructed to devalue our natural being, the Christian God is a projection of value from the viewpoint of the ascetic ideal (see §6 of this entry). That this God is dead amounts to a prediction that Christian theism, along with the ascetic ideal that forms its basis, is nearing its end as a major cultural force and that its demise will be brought about by forces that are already and irreversibly at work.

One such force, to which Nietzsche himself contributed, is the development of atheism in the West, a development that stems from Christian morality itself and the will to truth it promotes. The will to truth, a commitment to truth ‘at any price’, is the latest expression of the ascetic ideal, but it also undermines the whole Christian worldview (heaven, hell, free will, immortality) of which ‘God’ is the symbol. Inspired by the will to truth, philosophy since Descartes has progressively undermined the arguments that supported Christian doctrines, and science has given us reason to believe that we can explain all the explicable features of empirical reality without appealing to God or any other transcendent reality. Theism has thus become cognitively superfluous. In this situation we can justify atheism without demonstrating the falsity of theism, Nietzsche claims, if we also have a convincing account of how theism could have arisen and acquired its importance without being true. Even if there is no cognitive basis for belief in God, however, might not one still accept something on the order of William James’ will to believe? (see James, W. §4). Nietzsche nowhere treats this option as irrational, but he does deny that it is now a serious option for those who have taken most strictly and seriously Christianity’s ascetic morality. It may not be irrational, but it is psychologically impossible, Nietzsche thinks, to accept theism if the commitment to truthfulness has become fully ingrained, if hardness against oneself in matters of belief has become a matter of conscience. Atheism is ‘the awe-inspiring *catastrophe* of a two-thousand year discipline in truth that finally forbids itself the *lie involved in belief in God*’ (*Genealogy* III §27 [*Werke* VI.2: 427]).

Although atheism, especially among the most spiritual and intellectual human beings, undoubtedly weakens Christianity, depriving it of both creative energy and prestige, it does not bring about the death of God by itself. The modern world, as Kierkegaard had seen already, contains many other factors that weaken the influence of Christianity and its ideal; among these Nietzsche includes the development of money-making and industriousness as ends in themselves, democracy, and the greater availability to more people of the fruits of materialistic pursuits. Zarathustra’s statement that ‘when gods die, they always die several kinds of death’ suggests that just as the ascetic ideal has been accepted by different kinds of people for different reasons, the death of God and the ascetic ideal is also brought about by a multiplicity of causes that operate differently on different kinds of people. What matters, says Zarathustra, is that ‘he is gone’ (*Zarathustra* IV §6 [*Werke* VI.1: 320]).

According to Nietzsche, the loss of belief in God will initiate a ‘monstrous logic of terror’ as we experience the collapse of all that was ‘built upon this faith, propped up by it, grown into it; for example, the whole of our European morality’ (*Gay Science* §343 [*Werke* V.2: 255]). In notes made late in his career (published in *The Will to Power*), Nietzsche calls this collapse of values ‘nihilism’, the ‘radical repudiation of value, meaning, and desirability’. He predicts ‘*the advent of nihilism*’ as ‘the history of the next two centuries’, and calls himself ‘the first perfect nihilist of Europe’. However, he adds that he has ‘lived through the whole of nihilism, to the end, leaving it behind’ (*Will to Power* Preface [*Werke* VIII.2: 431-2]). Nihilism is therefore not his own doctrine, but one he diagnoses in others (including his own earlier self). He *does not* believe that nothing is of value (or that ‘everything is permitted’) if God does not exist, but that this form of judgment is the necessary outcome of the ascetic ideal. Having come to believe that the things of the highest value - knowledge, truth, virtue, philosophy, art - must have a source in a reality that transcends the natural world, we necessarily experience these things as devoid of value once the ascetic ideal itself leads to the death of God, to the denial that any transcendent reality exists.

8 Morality

Nietzsche’s criticism of morality is perhaps the most important and difficult aspect of his later philosophy. Calling himself an ‘immoralist’ - one who opposes all morality - he repeatedly insists that morality ‘negates life’. He turned against it, he claims, inspired by an ‘instinct that aligned itself with life’ (*Birth of Tragedy Preface 5* [*Werke* III.1: 13]). Whatever Nietzsche might mean by suggesting that morality is ‘against life,’ his point is *not* that morality is ‘unnatural’ because it restricts the satisfaction of natural impulses. He finds what is natural and ‘inestimable’ in any morality in the hatred it teaches of simply following one’s impulses, of any ‘all-too-great

freedom': it teaches 'obedience over a long period of time and in a single direction' (*Beyond Good and Evil* §188 [*Werke* VI.2: 110-11]). Nietzsche analyses the directive to 'follow nature' as commanding something that is either impossible (if it means 'be like the nonhuman part of nature') or inevitable (if it means 'be as you are and must be').

His objection to morality sometimes seems to be not that it is 'against life', but that it promotes and celebrates a kind of person in which he finds nothing to esteem: a 'herd animal' who has little idea of greatness and seeks above all else security, absence of fear, absence of suffering. To complicate matters still further, he sometimes uses 'morality' to refer to what he approves of, for instance, 'noble morality' and 'higher moralities'.

The last of these interpretive problems can be resolved by recognizing that Nietzsche uses 'morality' in both a wider and a narrower sense. Every ethical code or system for evaluating conduct is 'a morality' in the wider, but not in the narrower sense. A system that determines the value of conduct solely in terms of 'the retroactive force of success or failure', for instance, is an instance of 'morality' in the wider sense, but Nietzsche counts it as 'pre-moral' in the narrower sense (*Beyond Good and Evil* §32 [*Werke* VI.2: 46-7]). And it is the narrower sense Nietzsche is using when he commits himself to 'the overcoming of morality' and claims that it 'negates life'. His immoralism does not oppose all forms of ethical life. Although he opposes morality in the narrower sense, Nietzsche accepts another ethical system in terms of which he considers himself 'bound' or 'pledged'. Indeed, he claims that, contrary to appearances, 'we immoralists' are human beings 'of duty', having 'been spun into a severe yarn and shirt of duties [which we] *cannot* get out of' (*Beyond Good and Evil* §226 [*Werke* VI.2: 168]).

Why didn't Nietzsche just say that he opposed *some* moralities and call his own ethical system his 'morality'? He undoubtedly thought that would be more misleading than his use of the term in a dual sense because it would trivialize the radical nature of his position. He called himself an 'immoralist' as a 'provocation' that would indicate what distinguishes him from 'the whole rest of humanity' (*Ecce Homo* IV: §7 [*Werke* VI.3: 369]). And it could so function, he thought, even though he actually opposes morality only in the narrower sense, precisely because this is the sense 'morality' has had until now. That word has been monopolized, he thinks, for a particular kind of ethical system on which all our currently available choices for an ethics are mere variations.

Genealogy provides a genealogy of morality in the narrower sense (the sense 'morality' will have hereafter in this entry) and a complex and sophisticated analysis of that concept of morality. Although there is no agreed-upon definition, we all have a feeling for what 'morality' in this sense means. But both the feeling and the 'meaning' are actually products of a complicated historical development that synthesized meanings of diverse origins into a unity, one that is difficult to dissolve or analyse and impossible to define. If conceptual analysis were a matter of formulating necessary and sufficient conditions for the use of a term, we might analyse the concept of morality by specifying the characteristics that are both necessary and sufficient to qualify a code of conduct as 'a morality'. But this approach has never delivered great clarification, and Nietzsche's understanding of concepts explains why: our concepts need clarification precisely because they are products of a complicated historical development. Different strands have been tied together into such a tight unity that they seem inseparable and are no longer visible as strands. To analyse or clarify such a concept is to disentangle these strands so that we can see what is actually involved in the concept. History can play a role in analysing a concept because at earlier stages the 'meanings' that constitute it are not as tightly woven together and we can still perceive their shifts and rearrangements. Looking at the history of the corresponding phenomenon can therefore make it easier for us to pick out the various strands that make up the concept and better able to recognize other possible ways of tying them together. Nietzsche's genealogy of morality aims to show that there are distinct aspects of morality, each with a separate pre-moral source, which makes the synthesis we call 'morality' something that can be undone, so that its strands might be rewoven into a different form of ethical life.

The three essays of *Genealogy* separate out for examination three main strands of morality: the good (in the sense of virtue), the right (or duty), and a general understanding of value. Each essay focuses on the development of one strand without paying much attention to the other two, even though any developed form of ethical life will actually involve all three aspects in some form and interconnection. The overall account of morality constitutes a 'genealogy' precisely because it traces the *moral* version of each strand back to pre-moral sources - thus to *ancestors of morality*. Its upshot is that what we call 'morality' emerged from these pre-moral ancestors when the right and the good become tied together under the interpretation of value provided by the ascetic ideal. This

explains why Nietzsche claims that morality 'negates life': morality is an ascetic interpretation of ethical life.

The first essay in *Genealogy* finds the central pre-moral ancestor of morality's idea of goodness among politically superior classes in the ancient world whose members called themselves 'the good' and used 'good' and 'virtue' as their marks of distinction, the qualities that distinguished them from commoners or slaves. 'Good' and 'virtuous' were the same as 'noble' in the sense of 'belonging to the ruling class'; their contrasting term was 'low-born' or 'bad' (the German, *schlecht*, originally meant 'simple' or 'common').

As Nietzsche uses 'bad' (he does not claim to reflect contemporary usage), it involves no connotation of blame, whether applied to the poor person or the liar. 'Bad' certainly expresses a value judgment: that the person so described is inferior. The nobles regard themselves as superior and look down on the bad (sometimes with contempt, sometimes with pity). But they do not blame them for being inferior, or think that the inferior ought to be good (much less that inferiority deserves punishment or goodness a reward). Such judgments make sense only if one is judging inferiority in moral terms - that is, if 'bad' has become 'morally bad' or 'evil'.

To explain the origin of the good/evil (the specifically moral) mode of valuation, Nietzsche postulates a 'slave revolt in morality', a revaluation inspired by *ressentiment* (grudge-laden resentment) against the nobles. Nietzsche does not claim that the nobles' actions were considered wrong because they were resented. He is dealing only with ideas of goodness or virtue in this essay; he seeks to explain how goodness became connected to praise and blame, reward and punishment. His postulated 'slave revolt' was led not by slaves but by priests, the 'great haters' in human history precisely because their spirituality is incompatible with the direct discharge of resentment and revenge. They hated the nobles not because they were oppressed by them but because the nobles considered themselves superior and had been victorious over them for the respect and admiration of the people. Because this hatred could not be expressed directly, it grew to monstrous proportions until it finally found an outlet in revaluing the nobles and their qualities as inferior. As a result, certain qualities - useful to those in a slavish or dependent position - were called 'good', not because anyone found them particularly admirable, but from a desire to 'bring down' people with the opposite qualities. Simply 'looking down' at the nobles and their qualities would not have done the trick, especially since the majority envied and admired them. Only through the transformation of bad into evil, of inferiority into something for which one could be blamed, could the revaluation succeed. Pent-up *ressentiment* could then be vented in acts of blaming and moral condemnation, which Nietzsche sees as acts of 'imaginary revenge' that 'bring down' hated opponents 'in effigy' and elevate those who do the blaming, at least in their own imagination. Blaming, for Nietzsche, evidently involves the judgment that the person blamed is deserving of punishment, in this case for their inferiority. Therefore, once 'bad' is transformed into 'evil', God and his judgment along with heaven and hell can be used to support the revaluation by winning over to it those who would not feel sufficiently elevated by mere moral condemnation of the nobles. Nietzsche suggests that this is how the issue of free will became connected to morality. Blaming or holding people responsible for their actions does not raise the issue; it is raised by holding them responsible for what they are. And that is precisely what was required for the revaluation of noble values.

9 Morality (cont.)

Priests did not invent the idea of 'evil' on the spot, however. The notion of blame required for the revaluation emerged in a quite different sphere, that of right conduct or duty, the development of which Nietzsche sketches in the second essay of *Genealogy*. The pre-moral ancestor to which this essay traces moral versions of right and wrong, duty or obligation, is the ethics of custom (*Sittlichkeit der Sitte*), an early system of community practices that gained the status of rules through the threat of punishment. These rules were perceived as imperatives, but not as moral imperatives: violation was punished, but not considered to be a matter of conscience or thought to incur guilt.

Nietzsche finds an ancestor of guilt in the realm of trade, in the creditor-debtor relation. Guilt arises, Nietzsche claims, when the idea of debt is put to the uses of the 'bad conscience', the sense of oneself as unworthy, which develops when the external expression of aggressive impulses becomes restricted to such an extent that they can be expressed only by being turned back against the self. This internalization does not take place automatically, however; human beings must learn techniques that promote it, and Nietzsche views priests as the great teachers in this field. One such technique exploits the idea that a debt is owed to ancestors (who eventually come to be perceived as gods) for the benefits they continue to bestow and for violations of community laws which represent

their will. Priests use this idea to teach the people that they must make difficult sacrifices to the gods - for example, to sacrifice one's first-born - and that certain instances of apparent bad luck and suffering constitute the extraction of payment for violations of divine law, hence are deserved punishments.

So conceived, the debts are still mere debts, material rather than moral 'owings'. The moralization of debt (and thereby of duty) removes the idea that it can simply be paid off and connects it to one's worth or goodness. This moralization takes place by means of the third strand of morality analysed in *Genealogy*, the understanding of value, which in the case of morality is guided by the ascetic ideal. We enter what Nietzsche calls the 'moral epoch' only when the divine being to whom the debt is owed is considered the highest being and is conceived in non-naturalistic or ascetic terms, as a purely spiritual being and thus as a repudiation of the value of natural human existence (see §§6-7 of this entry). What must now be sacrificed to the divine is 'one's own strongest instincts, one's "nature"' (*Beyond Good and Evil* §55 [*Werke* VI.2: 72]). The affirmation of these instincts is conceived as rebellion against God, and the normal sufferings of human life as punishments for this rebellion. The debt is now owed precisely for what one is and continues to be, for being part of the natural world. This debt can no longer be considered material, a mere debt, for while it is owed and payment must be made, it can never be paid off. And the punishment one deserves is now completely bound up with one's (lack of) goodness or virtue, which is interpreted in ascetic terms as self-denial, the denial of one's natural impulses, or at least as selflessness.

The priest now has the notion of 'evil' required for the revaluation of the noble values: the moralized notion of virtue as self-denial provides the standard against which the nobles could be judged inferior, whereas the moralized notion of debt provides the basis for blaming the nobles for that inferiority. Both notions (of virtue and duty) were moralized by being tied together under the understanding of value provided by the ascetic ideal. Morality connects duty and virtue in such a way that blameable violations of duty are taken to show lack of virtue and lack of virtue is blameable (luck has nothing to do with it). Because he sees this connection as having been brought about by means of the ascetic ideal, Nietzsche regards that ideal as a major element of morality.

His own ideal is a very different one. Named after the Greek god Dionysus, Nietzsche's ideal celebrates the affirmation of life even in the face of its greatest difficulties, and thus gives rise to a doctrine and valuation of life that is fundamentally opposed to the one he finds behind morality. Committed to finding the sources of value in life, he rejects all non-naturalistic interpretations of ethical life, those that make reference to a transcendent or metaphysical world. It therefore seems likely that what he opposes in morality is not the idea of virtue, or standards of right and wrong, but the moralization of virtue and duty brought about by the ascetic ideal. Morality 'negates life' because it is an ascetic interpretation of ethical life. By interpreting virtue and duty in non-natural terms, it reveals the assumption of the ascetic ideal: that things of the highest value must have their source 'elsewhere' than in the natural world. This is why Nietzsche says that what 'horrifies' him in morality is 'the lack of nature, the utterly gruesome fact that *antinature* itself received the highest honours as morality and was fixed over humanity as law and categorical imperative' (*Ecce Homo* IV: §7 [*Werke* VI.3: 370]).

But how is this connected to Nietzsche's complaints against 'herd morality'? 'Herd' is his deliberately insulting term for those who congregate together in questions of value and perceive as dangerous anyone with a will to stand alone in such matters. He calls the morality of contemporary Europe 'herd animal morality' because of the almost complete agreement 'in all major moral judgments'. Danger, suffering, and distress are to be minimized, the 'modest, submissive, conforming mentality' is honoured, and one is disturbed by 'every severity, even in justice'. Good-naturedness and benevolence are valued, whereas the 'highest and strongest drives, if they break out passionately and drive the individual far above the average and the flats of the herd conscience,' are slandered and considered evil (*Beyond Good and Evil* §§201-2 [*Werke* VI.2: 123-7]).

This morality does not seem to involve the ascetic ideal. In fact, it is more likely to be packaged as utilitarianism, which offers a naturalistic, and therefore presumably unascetic, interpretation of duty and virtue, in terms of happiness (see Utilitarianism). We might, in fact, formulate Nietzsche's main objection to herd morality as a complaint that there is nothing in it to play the role of the ascetic ideal: to hold out an ideal of the human person that encourages individuals to take up the task of self-transformation, self-creation, and to funnel into it the aggressive impulses, will to power and resentment that would otherwise be expressed externally. Although it horrifies him, Nietzsche recognizes the greatness of the ascetic ideal. It is the only ideal of widespread cultural importance human beings have had so far, and it achieved its tremendous power, even though it is the 'harmful

ideal *par excellence*', because it was necessary, because there was nothing else to play its role. 'Above all, a counterideal was lacking - until Zarathustra' (*Ecce Homo* III GM [*Werke* VI.3: 352]).

The problem is that the ascetic ideal is now largely dead (as part of the 'death of God'). Nietzsche thinks we need something to replace it: a great ideal that will inspire the striving, internalization, virtue, self-creation that the ascetic ideal inspired. 'Herd animal morality' is what we are left with in the absence of any such ideal. It is what morality degenerates into once the ascetic ideal largely withdraws from the synthesis it brought about. The virtuous human being no longer is anything that can stir our imagination or move us. For Nietzsche, this is the 'great danger' to which morality has led: the sight of human beings makes us weary.

10 The overhuman (*Übermensch*)

Nietzsche's apparent alternative to 'herd-animal morality' is his most notorious idea, the Übermensch. (There is no really suitable English translation for this term: 'overhuman' has been chosen instead of 'superman' or 'overman' because it seems best able to bring out the idea of a being who overcomes in itself what has defined us as human.) The idea actually belongs to the protagonist of *Thus Spoke Zarathustra*, Nietzsche's work of philosophical fiction, and it can never be assumed that Zarathustra's ideas are the same as those of Nietzsche. As the story opens, Zarathustra is returning from ten years of solitude in the wilderness, bringing human beings a gift: his teaching that humanity is not an end or goal, but only a stage and bridge to a higher type of being, the overhuman. He teaches that now that God is dead, it is time for humanity to establish this higher type as the goal and meaning of human life, a goal that can be reached only if human beings overcome what they now are, overcome the merely human.

The idea of becoming a higher kind of being by overcoming one's humanity can seem frightening. For some, it calls up images of Nazi stormtroopers seeking out 'inferior' human beings to annihilate. However, *Zarathustra* suggests that Nietzsche has something very different in mind. 'Zarathustra' is another name for Zoroaster, the founder of Zoroastrianism (see Zoroastrianism). Nietzsche claims that the historical Zarathustra 'created the most calamitous error, morality', because his doctrine first projected ethical distinctions into the metaphysical realm (as a cosmic fight between good and evil forces). Nietzsche bases his character on Zarathustra because the creator of the error 'must also be the first to recognize it' (*Ecce Homo* IV §3 [*Werke* VI.3: 365]).

Zarathustra is thus the story of a religious leader, the inventor of one of the world's oldest religions, who comes to recognize the 'error' of traditional (moralized) religions. Far from turning against every aspect of traditional religion, however, Zarathustra commits himself to its central task: urging human beings to raise their sights above their usual immersion in materialistic pursuits to recognize the outlines of a higher form of being that calls them to go beyond themselves, to become something more than they are. Zarathustra's overhuman can thus be seen as a successor to the images of 'higher humanity' offered by traditional religions. His teaching is not intended to encourage human beings to throw off the constraints and shackles of morality (something Nietzsche sees as well underway without his help). Its point is, rather, to combat the forces of barbarism by encouraging us to take on a more demanding ethical task than modern morality requires: that of becoming what Nietzsche had earlier called a 'true human being'. When he used that phrase, however, Nietzsche believed it applied only to 'those no-longer animals, the philosophers, artists, and saints'. Animal (purely natural) existence was a senseless cycle of becoming and desire, and only those who escape it by extinguishing egoistic desire counted as truly human. The saint in particular counted as 'that ultimate and supreme becoming human', in which 'life no longer appears senseless but appears, rather, in its metaphysical meaningfulness' (*Unfashionable Observations* III §5 [*Werke* III.1: 371-9]). From the viewpoint of his later philosophy, early Nietzsche's conception of true humanity is an obvious expression of the ascetic ideal; it devalues natural existence relative to something that is its opposite. Once one recognizes this opposite as unattainable (as Nietzsche did in *Human*), the conception can be seen for what it really is: a devaluation and condemnation of human life.

Nietzsche never abandoned his early belief that the modern world is threatened by forces of both conformism and barbarism and that our great need is therefore for educators who will inspire human self-overcoming by the force of a lofty ideal. But since he rejects the ascetic ideal, he must abandon his earlier image of a true human being. At the end of *Genealogy*'s second essay, Nietzsche suggests that what the overhuman overcomes is not the 'natural' inclinations against which the ascetic ideal has been directed, those that make apparent our connection to other animals, but rather the 'unnatural' inclinations, the aspirations to a form of existence that transcends nature and animality. In other words, the overhuman must overcome all the impulses that led human beings to accept the

ascetic ideal, an ideal that has so far defined what counts as 'human'. As we will see in §2, however, Zarathustra's call for the overcoming of the human is still too bound up with the old ideal.

11 The will to power

Zarathustra teaches that life itself is will to power, and this is often thought to be Nietzsche's central teaching as well. However, will to power first appears in Nietzsche's work in *Daybreak* (1881), and there it is one human drive among others, the striving for competence or mastery. It is usefully thought of as a second-order drive or will: a need or desire for the effectiveness of one's first-order will. In *Daybreak*, Nietzsche finds this drive at work in large areas of human life: in asceticism, revenge, the lust for money, the striving for distinction, cruelty, blaming others, blaming oneself. He explains the drive's apparent omnipresence in human life by saying not that life is will to power (or that power is the only thing humans want), but that power has a special relation to human happiness. He calls love of power a 'demon' because human beings remain unhappy and low-spirited if it is not satisfied even if all their material needs are satisfied, whereas power can make them as happy as human beings can be, even if everything else is taken away (*Daybreak* §262 [*Werke* V.1: 211]). In *Genealogy* (1887) he expresses a similar idea in more positive terms when he calls the will to power 'the most life-affirming drive', that is, the one whose satisfaction contributes most to finding life worth living (*Genealogy* III §18 [*Werke* VI.2: 383]).

Zarathustra claims that this 'will to be master' is found in all that lives, and that this explains why life is 'struggle and becoming', always overcoming itself, always opposing what it has created and loved: 'Verily, where there is perishing and a falling of leaves, behold, there life sacrifices itself - for power' (*Zarathustra* II §12 [*Werke* VI.1: 144-5]). But this seems a clearly anthropomorphic conception of life, the projection of the human will to power onto nonhuman nature. Nietzsche rejects anthropomorphic conceptions of nature, insists that will is to be found only in beings with intellects, and complains that Schopenhauer's idea of will 'has been turned into a metaphor when it is asserted that all things in nature possess will' (*Human* II §5 [*Werke* IV.3: 18]).

Yet Nietzsche does say that life, and even reality itself, is will to power. The idea seems to be that reality consists of fields of force or dynamic quanta, each of which is essentially a drive to expand and thus to increase its power relative to all other such quanta. However, almost all the passages to this effect are found in Nietzsche's notebooks. He actually argues that reality is will to power in only one passage he chose to publish, and this passage gives us good reason to doubt that Nietzsche actually accepted the argument. He neither says nor implies that he accepts its conclusion, and he argues against its premises in earlier passages of the same book (*Beyond Good and Evil* §36 [*Werke* VI.2: 50-1]).

Why would Nietzsche construct a rather elaborate argument from premises he clearly rejects? Perhaps it was to illustrate the view of philosophy presented earlier in the same book. Philosophers' ultimate aim, he claims, is not to obtain knowledge or truth, but to interpret the world in terms of their own values (see §6 of this entry) - to 'create [in thought] a world before which [they] can kneel' (*Zarathustra* II §12 [*Werke* VI.1: 143]). Yet they present their interpretations as true, and argue for them on the basis of amazingly 'little': 'any old popular superstition from time immemorial', a play on words, a seduction by grammar, or 'an audacious generalization of very narrow, very personal, very human, all too human facts' (*Beyond Good and Evil* Preface [*Werke* VI.2: 3-4]). This seems an apt diagnosis of Nietzsche's own argument, since he elsewhere identifies its first premise as 'Schopenhauer's superstition' and the exaggeration of a popular prejudice, and its second and third premises as part of the 'primeval mythology' Schopenhauer 'enthroned' (*Beyond Good and Evil* §§16-19 [*Werke* VI.2: 22-6]; *Gay Science* §127 [*Werke* V.2: 160]). Furthermore, the effect of the argument is an 'audacious generalization' to the whole universe of the will to power, which Nietzsche originally understands as one human drive among others. In generalizing this drive, Nietzsche can be seen as generalizing and glorifying what he values, just as he claims philosophers have always done and must do. For Nietzsche's own answer to 'what is good?' is 'everything that heightens the feeling of power in human beings, the will to power, power itself' (*Antichrist* §2 [*Werke* VI.3: 168]).

Why does Nietzsche value the will to power? He certainly came to recognize it as responsible for the violence and cruelty of human life and as the prime ingredient in what he had earlier called the 'cauldron full of witches' brew' that threatens the modern world with 'horrible apparitions' (*Unfashionable Observations* III §4 [*Werke* III.1: 363]). But he also saw it as 'the most life-affirming drive' and as responsible for the great human accomplishments - political institutions, religion, art, morality and philosophy. His basic psychological claim is that human beings are subjected to intense experiences of powerlessness and that such experience leads to depression unless some

means is found for restoring a feeling of power. What we call ‘barbarism’ is largely a set of direct and crude strategies for restoring the feeling of power by demonstrating the power to hurt others. What we call ‘culture’ is a set of institutions and strategies for achieving the same feeling in a sublimated or less direct fashion. The most important strategies have all involved directing the will to power back against the self. Such internalization is responsible for all the ethical achievements of human life, all the ways in which human beings have changed and perfected their original nature by taking on a new and improved nature. But the internalization of the will to power has been promoted by the ascetic ideal’s condemnation of our original nature, especially of the will to power. This is what Zarathustra attempts to overcome with his overhuman teaching, which directs the will to power back against the self to overcome the inclinations that led to the old ideal. He therefore does not condemn the will to power, but celebrates it.

12 Eternal recurrence

Nietzsche identifies himself above all else as the teacher of eternal recurrence, which is often interpreted as a cosmological theory to the effect that the exact history of the cosmos endlessly repeats itself. Although he did sketch arguments for such a theory in his notebooks, he actually does not argue for or commit himself to a recurrence cosmology in any work he published. And, although he presents eternal recurrence as the ‘basic conception’ of *Zarathustra*, he does not commit its protagonist to a cosmology. He identifies this ‘basic conception’ not as a cosmology, but as ‘the highest formula for affirmation that is at all attainable’ (*Ecce Homo* III §1 [*Werke* VI.3: 335]).

As first articulated in *Gay Science*, eternal recurrence is a heuristic device used to formulate Nietzsche’s Dionysian ideal (see §9 of this entry). How well disposed we are to life is to be measured by how we would react upon being told by a demon (in a manner designed to induce uncritical acceptance) that we will have to live again and again the exact course of life we are now living. Would we experience despair or joy, curse the demon or greet him as a god? Nietzsche’s ideal is the *affirmation of eternal recurrence*, to be a person who would respond to the demon with joy. This is *not* equivalent to having no regrets, since it has no implication concerning how to respond if given the choice of variations on history. Nietzsche’s ideal is to love life enough to be joyfully willing to have the whole process repeated eternally, including all the parts that one did not love and even fought against. Eternal recurrence gives him a formula for what it is to value the process of life as an end and not merely as a means.

Nietzsche’s special self-identification with eternal recurrence can be explained in terms of his view regarding the importance of the ascetic ideal and his explanation of its power: ‘a *counterideal* was lacking - until Zarathustra’. There are only two plausible candidates for the counterideal Zarathustra offers, the overhuman and the affirmation of eternal recurrence. The overhuman is one who overcomes the ascetic ideal. But, as Zarathustra first preaches it, the overhuman ideal can be seen as another variation on the ascetic ideal. Like the ascetic priest, Zarathustra treats our lives as valuable only as a means to a form of life that is actually their negation. Like the ascetic priest, he turns his will to power against human life and takes revenge against it (for the powerlessness it induces) by excluding it from what he recognizes as intrinsically valuable. The ideal of affirming eternal recurrence, in contrast, values the whole process of living, and thereby overcomes the ascetic ideal’s devaluation of human life, even while pushing us to go beyond its present form. It provides us with the image of a higher form of human life, but does not take revenge against the latter by refusing to call its higher form ‘human’. It therefore appears to be Zarathustra’s true alternative to the ascetic ideal.

It may seem, however, that happy pre-moral barbarians should be able to affirm eternal recurrence. How then can it provide an image of a higher form of human life towards which to strive, one that could inspire internalization, virtue and self-creation comparable to that inspired by the ascetic ideal? One relevant factor is Nietzsche’s hope for new philosophers who will create new values. Perhaps he did not expect his counterideal to provide the full content of new values, just as the ascetic ideal did not provide the full content of the old values. The ascetic priests did not create their values from scratch. They took over virtues, duties, forms of life that were already there and gave them a new interpretation, one that denied the value of natural human existence. Nietzsche seems to hope that new philosophers will do something comparable - that they will provide a new life-affirming interpretation of virtues, duties and forms of life that are already there. Eternal recurrence would function as the form of new values, a test that they must pass to count as non-ascetic or life-affirming. The test for teachers of new values would be: can you endorse and teach these values while affirming eternal recurrence?

If this suggestion is correct, Nietzsche's relation to the modern world is not quite as revolutionary as it sometimes appears. The role of his new philosophers is not to overturn everything, but to take what is in pieces due to the dissolution of the old interpretation of value and to provide a new interpretation. This kind of philosophizing is not just for the future, but is found in Nietzsche's own writings. He praises old virtues - justice and generosity, for instance - but gives us a new interpretation of them, a different way of seeing them as valuable. Generosity is valuable not because it is selfless, but because it exhibits the soul's richness and power. And justice is perhaps the greatest virtue not because it is disinterested or obeys a higher law, but because it is the rarest and highest mastery that is possible on earth. And Nietzsche does not merely talk about these matters. His writings show us a new kind of person and a new kind of philosopher in the virtues he exhibits in them, not least of all in the interpretations he gives of his virtues. Truthfulness or honesty, justice, generosity are all exhibited in his writings, but are given life-affirming interpretations that bring to our attention the role of the will to power in them.

This is not to say that Nietzsche's new values are simply repackaged old ones. Nietzsche's ideal leads him to value qualities that he claims have never before been considered part of greatness, such as malice, exuberance and laughter. But even in their new interpretations of old values, the aim of Nietzsche's new philosophers is to push culture in new directions, for instance, towards giving explicit expression at the higher levels of culture to what the old ideal excluded from the highest forms of life. This is what Nietzsche exhibits, for instance, in the positive and negative emotion, the exuberance and malice, the aggression and eros, that permeates his writings. At this level, his philosophy is art, but it is an art that completes and is no longer used to devalue knowledge, which can now be recognized as its sometimes contentious partner in Nietzsche's soul and writings.

List of works

Nietzsche, F. (1967-84) *Werke: Kritische Gesamtausgabe (Complete critical works)*, ed. G. Colli and M. Montinari, Berlin: de Gruyter.(Now the standard German edition of Nietzsche's works. Volumes of the critical apparatus are still appearing, but the books and *Nachlaß* were completed by 1984. A paperback edition of the essentials appeared in 1980 as *Sämtliche Werke*.)

Nietzsche, F. (1872) *Die Geburt der Tragödie*; trans. W. Kaufmann and R. Hollindale as *The Birth of Tragedy*, in *Basic Writings of Nietzsche*, New York: Modern Library, 1968. (Nietzsche's first book, written under the influence of Wagner and Schopenhauer, with 'Attempt at a Self-Criticism', a preface written for the second edition of 1886. Important source for Nietzsche's early views of art and of the Dionysian, but too bound up with the thesis that art is more truthful than science to represent Nietzsche's later view.)

Nietzsche, F. (1873-6) *Unzeitgemäße Betrachtungen*; trans. R. Gray as *Unfashionable Observations*, Stanford, CA: Stanford University Press, 1995.(Four essays of cultural criticism from Nietzsche's early period, in which he is still trying to elevate art over science. These essays exhibit Nietzsche's early philosophy as a critique of modern culture, and the essays on history and Schopenhauer point forward to his later ideas of eternal recurrence and the overhuman. This work has also been translated as 'Untimely Meditations' and 'Unmodern Observations'.)

Nietzsche, F. (1878-80) *Menschliches, Allzumenschliches*; trans. R. Hollingdale as *Human, All Too Human*, intro. R. Schacht, Cambridge: Cambridge University Press, 1996. (Represents the beginning of Nietzsche's middle period, his turn away from Wagner, art and metaphysics, and his embrace of science and a thoroughgoing naturalism. Contains his first, relatively crude, attempts at a naturalistic understanding of moral values.)

Nietzsche, F. (1881) *Morgenröte*; trans. R. Hollingdale as *Daybreak*, ed. M. Clark and B. Leiter, Cambridge: Cambridge University Press, 1997.(The second work of Nietzsche's middle period, it represents the true beginning of Nietzsche's own way in philosophy. He called it the beginning of his 'campaign against morality,' and it contains much of his psychology of the will to power. This work has also been translated as 'Dawn'.)

Nietzsche, F. (1882) *Die Fröhliche Wissenschaft*; trans. W. Kaufmann as *The Gay Science*, New York: Vintage, 1974.(The work that inaugurates Nietzsche's final period, it announces the 'death of God' and contains Nietzsche's first formulation of his idea of eternal recurrence. Book Five, added in the second edition of 1887, contains some of Nietzsche's most important reflections on science and its connection to democracy. This work has also been translated as 'Joyful Wisdom'.)

Nietzsche, F. (1883-5) *Also Sprach Zarathustra*; trans. W. Kaufmann as *Thus spoke Zarathustra*, in *The Portable Nietzsche*, New York: Viking, 1954.(Nietzsche's work of philosophical fiction and the major source for the cosmological version of the will to power and the ideas of the overhuman and eternal recurrence. Not easily

understood without knowledge of Nietzsche's other books.)

Nietzsche, F. (1886) *Jenseits von Gut und Böse*; trans. W. Kaufmann and R. Hollingdale as *Beyond Good and Evil*, in *Basic Writings of Nietzsche*, New York: Modern Library, 1968.(Nietzsche at the height of his powers on philosophy and science, religion, morality, politics, nationality and nobility. A true masterpiece, but difficult.)

Nietzsche, F. (1887) *Zur Genealogie der Moral*; trans. M. Clark and A. Swensen as *On the Genealogy of Morality*, Indianapolis, IN: Hackett Publishing Company, 1997.(Nietzsche's most detailed analysis of and most important treatment of morality, considered by him as probably the most accessible introduction to his work and the 'touchstone' of what 'belongs' to him. Contains his most sustained discussion of the ascetic ideal, and was intended to clarify the title and contents of *Beyond Good and Evil*. This work has also been translated as 'On the Genealogy of Morals'.)

Nietzsche, F. (1888a) *Der Fall Wagner*; trans. W. Kaufmann and R. Hollingdale as *The Case of Wagner*, in *Basic Writings of Nietzsche*, New York: Modern Library, 1968.(Finished at the beginning of his final year, this is an often very funny book, and a major source for Nietzsche's views of Wagner and art.)

Nietzsche, F. (1888b) *Die Götzen-Dämmerung*, 1889; trans. W. Kaufmann as *The Twilight of the Idols*, in *The Portable Nietzsche*, New York: Viking, 1954.(Contains Nietzsche's final accounts of truth and knowledge, as well as important sections on morality and art. Fairly straightforward and more accessible than many of his other works.)

Nietzsche, F. (1888c) *Der Antichrist*, 1895; trans. W. Kaufmann as *The Antichrist*, in *The Portable Nietzsche*, New York: Viking, 1954.(Nietzsche's version of 'Why I am not a Christian'. Distinguishes original Christianity from the Pauline version and gives a relatively sympathetic portrait of the former and of the one who lived it. Fairly straightforward and accessible.)

Nietzsche, F. (1888d) *Ecce Homo*, 1908; trans. W. Kaufmann and R. Hollingdale in *Basic Writings of Nietzsche*, New York: Modern Library, 1968.(Nietzsche's autobiographical work, written in the middle of his final year, includes his own invaluable accounts of all his earlier works under the title 'Why I write such good books'. An important source for his view of art since the autobiography is clearly intended as a work of art.)

Nietzsche, F. (1888e) *Nietzsche contra Wagner*, 1895; trans. W. Kaufmann in *The Portable Nietzsche*, New York: Viking, 1954.(Nietzsche's last and shortest book, this is a compilation of passages from earlier works designed to show that Nietzsche and Wagner are 'antipodes'. A source for Nietzsche's final view of art and of the ways in which the art he promotes differs from Wagner's.)

Nietzsche, F. (1906) *Der Wille zur Macht*,; trans. W. Kaufmann as *The Will to Power*, New York: Viking, 1967. (Although treated by many, including Nietzsche's sister, as his magnum opus, this is not a book by Nietzsche. Rather, it is a collection of outlines, notes and jottings from his notebooks of 1883-8, selected and arranged by his sister and editors appointed by her.)

Nietzsche, F. (1975-84) *Briefwechsel: Kritische Gesamtausgabe*, ed. C. Colli and M. Montinari, Berlin: de Gruyter.(An edition of the complete letters to and from Nietzsche (the Nietzsche side of the correspondence was published in 1986 as *Sämtliche Briefe*). A 1969 English edition of selected letters, translated by Christopher Middleton, is reprinted as *Selected Letters of Friedrich Nietzsche*, Indianapolis, IN: Hackett Publishing Company, 1996.)

Nietzsche, F. (1979) *Philosophy and Truth: Selections from Nietzsche's Notebooks of the early 1870's*, trans. D. Breazeale, Atlantic Highlands, NJ: Humanities Press.(A valuable collection of material from the *Nachlaß* of the period surrounding the publication of *The Birth of Tragedy*. Includes 'Über Wahrheit und Lüge im aussermoralischen Sinne', trans. as 'On Truth and Lies in a non-moral sense', a widely known essay in which Nietzsche argues that, except for tautologies, all truths are 'illusions'.)

References and further readings

Ansell-Pearson, K. (1994) *An Introduction to Nietzsche as Political Thinker*, Cambridge: Cambridge University Press.(A lively introduction to Nietzsche's political thought.)

Clark, M. (1990) *Nietzsche on Truth and Philosophy*, Cambridge: Cambridge University Press.(An account of the development of Nietzsche's thinking about truth which forms the basis of the present entry. Includes chapters on truth and the ascetic ideal, the will to power and eternal recurrence.)

Deleuze, G. (1962) *Nietzsche et la philosophie*; trans. H. Tomlinson as *Nietzsche and Philosophy*, New York: Columbia University Press, 1983.(A reading of Nietzsche as anti-Hegelian; known especially for its influential distinction between active and reactive forces. An often difficult read.)

Derrida, J. (1978) *Éperons: Les Styles de Nietzsche*; trans. B. Harlow as *Spurs: Nietzsche's Styles*, Chicago, IL and London: University of Chicago Press, 1979.(Responds to Heidegger's interpretation of Nietzsche as a

metaphysician by playing with Nietzsche's texts rather than attempting to establish a truth about them. An example of philosophy as deconstruction. The translation is a French-English edition.)

Heidegger, M. (1961) *Nietzsche*, 2 vols; trans. D. Krell, San Francisco, CA: Harper & Row, 1979-82, 4 vols.(This interpretation of Nietzsche as a critic of metaphysics who was himself unable to avoid metaphysics has greatly influenced later Continental readings of Nietzsche; for advanced students who are as interested in Heidegger as in Nietzsche.)

(1950) *Nietzsche: Philosopher, Psychologist, Antichrist*, Princeton, NJ: Princeton University Press, 4th edn, 1974.(A landmark study that went a long way towards destroying the picture of Nietzsche as a Nazi sympathizer and an anti-Socratic irrationalist that once dominated the English-speaking world. Still useful for this purpose.)

Lange, F.A. (1866) *Geschichte des Materialismus und Kritik seiner Bedeutung in der Gegenwart*; trans. E.C. Thomas as *History of Materialism*, Boston, MA: Osgood, 1977, 3 vols.(A history of materialism from ancient Greece to 19th century Europe which Nietzsche read during his student days at Leipzig. A major influence on his views of science and knowledge.)

Morgen, G. (1941) *What Nietzsche Means*, New York: Harper & Row.(Still a valuable and very accessible introduction to all the main themes of Nietzsche's philosophy.)

Mueller-Lauter, W. (1971) *Nietzsche: Seine Philosophie der Gegensätze und die Gegensätze seiner Philosophie (Nietzsche's philosophy of contradictions and the contradictions of his philosophy)*, Berlin: de Gruyter. (Perhaps the most important German work on Nietzsche written after the Second World War; distinguishes the apparent from the real contradictions of Nietzsche's philosophy of the will to power, and argues that Nietzsche's thinking leads him to two very different versions of the overhuman. English translation in progress.)

Nehamas, A. (1985) *Nietzsche: Life as Literature*, Cambridge, MA: Harvard University Press.(Important attempt to relate Nietzsche's philosophical views to his literary styles, and the most important examination of how Nietzsche's books *exhibit* what this entry calls Nietzsche's 'ideal'. Its accounts of the will to power and eternal recurrence are alternatives to those given above.)

Richardson, J. (1996) *Nietzsche's System*, Oxford: Oxford University Press.(A systematic, challenging account of Nietzsche's thought that provides a more metaphysical alternative to the naturalistic Nietzsche of this entry, especially in its accounts of the will to power and perspectivism. Influenced by Continental readings of Nietzsche, especially those of Heidegger and Deleuze.)

Schacht, R. (1983) *Nietzsche*, London: Routledge & Kegan Paul.(Careful and detailed survey of all the main themes of Nietzsche's philosophy. Its Nietzsche has a basically naturalistic orientation, but nevertheless accepts the will to power as the basic principle of life.)

Schopenhauer, A. (1818) *Die Welt als Wille und Vorstellung*; trans. E.F.J. Payne as *The World as Will and Representation*, New York: Dover, 2 vols, 1969.(Perhaps the major philosophical influence on Nietzsche's thought and development.)

Young, J. (1992) *Nietzsche's Philosophy of Art*, Cambridge: Cambridge University Press.(Interesting account of Nietzsche's view of art; highly critical of Nietzsche *vis-à-vis* Schopenhauer.)

Nifo, Agostino (*c.*1470-1538)

Agostino Nifo was a university teacher, medical doctor and extremely prolific writer. His books included many commentaries on Aristotle's logic, natural philosophy and metaphysics, as well as original works on topics ranging from elementary logic to beauty and love. However, his most important works had to do with the human intellect, and with Averroes' view that there is just one intellect shared by all human beings. Although he never accepted Averroes' position as true, he did initially believe that Averroes correctly interpreted Aristotle on this point. He also entered into public controversy with Pomponazzi on the question whether human immortality could be proved. Nifo's Aristotelianism reflects his interest in many different traditions of commentary on Aristotle, including medieval Latin commentators, especially Thomas Aquinas, medieval Arab commentators and their Latin followers, especially John of Jandun, but most of all the Greek commentators. Here he shows the strong influence of Renaissance humanism, which made the Greek texts available. It was when Nifo himself learned Greek that he came to abandon the notion that Averroes was an accurate interpreter of Aristotle. Nifo was also very interested in Plato and Platonism, particularly as presented by Marsilio Ficino. His careful presentations of other people's doctrines were popular in university circles for much of the sixteenth century.

1 Life and works

Agostino Nifo (Eutychus Augustinus Niphus Suessanus) was born at Sessa Aurunca, near Caserta in southern Italy. After studying the liberal arts at Naples, he went on to Padua, where he received his degree around 1492. During his stay at Padua he gained the enmity of the Franciscan theologian Antonio Trombetta, a Scotist. He also engaged in a dispute with his teacher, Nicoletto Vernia, regarding the correct interpretation of Alexander of Aphrodisias' doctrine on the human soul (see Alexander of Aphrodisias). Presumably he was also on poor terms with Pietro Pomponazzi, who was his competitor by 1495. Pomponazzi scornfully criticizes Nifo in his own early questions on the soul.

Nifo left his post at Padua in 1499 and returned to his native town. There he witnessed the difficulties and trials resulting from the Spanish occupation. Nifo, who was also a practising medical doctor, was the personal physician of the Spanish Grand Captain in 1504. He seems to have taught at Naples in 1505 (where he moved in humanist circles), at Salerno in 1506-7, and again at Naples in 1507-8, when he unsuccessfully attempted to regain his post at Padua. In 1514 he taught at Rome. Subsequently he entered into controversy with his old rival Pomponazzi. Encouraged by Ambrogio Flandino to write a reply to Pomponazzi's *De immortalitate animae (On the Immortality of the Soul)*, which had been published in 1516, Nifo wrote a work with the same title that appeared in 1518. Pomponazzi replied in turn with his *Defensorium* (1519).

Nifo taught at Pisa for the Florentines from 1519 to 1522. He seems to have then taught at Salerno from 1522 to 1526 and again from 1533 to 1535; there is evidence that he taught at Naples in 1531-2. In 1535 he declined Pope Paul III's invitation to teach natural philosophy at Rome. He was elected mayor of his native town and extended a formal welcome to the Emperor Charles V when he visited Sessa Aurunca on 24 March 1536.

Nifo was an extraordinarily prolific writer, though very little of his work is available in a modern edition. His first work was an edition of the works of Aristotle and Averroes that appeared at Venice in 1495 and 1496. In 1497 this was followed by his own commentary on the *Destructio destructionum* (the medieval Latin translation of Averroes' *Tahafut al-tahafut (The Incoherence of Incoherence)*) and a treatise on the agent sense. While at Padua, he apparently finished a commentary on a Latin translation of Aristotle's *On the Soul* that was published against his wishes in 1503, the same year that he published his own important treatise on the intellect (*De intellectu*), which differs significantly from the commentary. He wrote a long sequence of commentaries on Aristotle's logical works, on Aristotle's works in natural philosophy, and on Aristotle's *Metaphysics* (see Aristotle). In 1520 he published a textbook in elementary logic, the *Dialectica ludicra (Playful Dialectics)*. He paid some attention to political philosophy, and published *De regnandi peritia (On the Practical Knowledge of Ruling)* (1522), a free adaptation of Machiavelli's *Il principe (The Prince)* (see Machiavelli, N. §2). He also wrote on humanist topics, including a work on beauty and love which he finished at his villa Niphanus in 1529. In them he attempted to give an Aristotelian theory of beauty and love in competition with that of Plato and his followers. He finished his commentary on Aristotle's books *On Animals* in 1534. Many of Nifo's Aristotle commentaries continued to be

published for at least three decades after his death.

2 Natural philosophy

Nifo showed an interest in natural philosophy from the beginning. In his early commentary on Averroes' *Destructio destructionum* he emphasizes that inasmuch as natural philosophy takes the senses as its starting point, it cannot reach a knowledge of God's act of creation, which is a form of making that is totally beyond sense knowledge. It was thus a grievous error on the part of the medieval Christian philosopher-theologians, the Latin Expositors (*expositores latini*), to have attributed a doctrine of creation to Aristotle. He was also concerned about the relationship between natural philosophy or natural science (*naturalis scientia*) and metaphysics, arguing that natural philosophy was subordinate to metaphysics. It is true that the existence of God and the separate substances (or purely immaterial beings) is demonstrated by natural philosophy on the basis of eternal motion. However, the existence of these beings is studied in a more complete fashion in metaphysics, which thus takes us beyond natural philosophy.

Nifo's commentary (1508) on Aristotle's *Physics* is remarkable for what it shows of his changing use of sources in response to a newly acquired mastery of Greek. Nifo openly admits that in his youth he asserted that the position of Averroes on the intellect is the same as that of Aristotle (see Averroism), but he explains that after having read and examined Aristotle's words in the Greek he came to see that Averroes' position is nonsense (*deliramentum*). Because Averroes, who did not know Greek, was working with erroneous translations which he could not correct, he misrepresents Themistius and generally acts like a drunkard. Nifo even stresses that he prefers himself to err with the Greeks in explicating a Greek author, rather than to think correctly with barbarians who lack command of the language. In the commentary, Nifo makes frequent reference to the Greek commentators on Aristotle, namely Alexander of Aphrodisias, Simplicius, Themistius and John Philoponus, who are all mentioned in his preface. In the same place however, he states his strong commitment to Aquinas, his 'trustworthy leader', to whom he gives, following John of Jandun and others, the honorific title of 'the Expositor'.

In both the commentary on Averroes and the commentary on the *Physics*, Nifo also mentions the Oxford Calculators (see Oxford Calculators). In the earlier commentary, he dismisses their work on the grounds that they follow mathematical principles and not natural principles. In the later work, he remarks that the Peripatetics (see Peripatetics) never dreamed of such a doctrine as that of the intension and remission of forms; it is a new question invented by idle men who want to be noticed.

3 Psychology

Both of Nifo's earliest works, the treatise on the agent sense and the commentary on Averroes' *Destructio destructionum*, treat psychological topics. The first treatise takes up the question of whether an agent sense is required in the process of sensation. Aristotle had argued that an agent intellect is required to initiate the process of understanding, and John of Jandun had argued that, in a parallel manner, an agent sense is required to initiate the process of sense perception. The activity of external objects and their impact on our passive sense organs via the reception of sensible species is not enough to explain how perception can occur. Nifo argues that Jandun was wrong. In the second treatise, he argues that Averroes' doctrine of the unity of the intellect - which is that all human beings share one intellect - is the correct interpretation of Aristotle. He calls Averroes 'Aristotle transposed' and 'Aristotle's priest'.

In his early commentary (published in 1503) on Aristotle's *On the Soul*, Nifo continues his praise of Averroes, whom he calls 'the Arab Aristotle' (see Ibn Rushd), and his attacks on John of Jandun. This time he asserts that John of Jandun was wrong in believing that Averroes acknowledged the existence of intelligible species as part of the process of understanding. Other striking positions that Nifo adopts are his belief that according to philosophy one can achieve an intuitive knowledge of God during this life, and his insistence that according to Aristotle and Averroes there is no real distinction between psychological faculties, notably the intellect and the will. He uses the phrase 'potestative whole' (*totum potestativum*) of the human soul, thus emphasizing his view that it is a single power, and also reflecting the influence of Albert the Great. In the commentary, Nifo shows a close knowledge both of Themistius' paraphrases on Aristotle's *On the Soul* in the translation of Ermolao Barbaro and of a now lost Latin translation of the commentary on *On the Soul* traditionally attributed to Simplicius. He compares both these sources to Plotinus, whom he knew from Marsilio Ficino's translation of the Enneads and commentary (see Ficino,

M.).

In 1503 Nifo published *De intellectu (On the Intellect)*, his major psychological work. Book I is divided into five treatises (*tractatus*) that are devoted to fundamental topics: the origin and immortality of the soul, the nature of the soul's separability from the body, the unity of the soul, the agent and possible intellects, and the speculative and practical intellects. At the end of each treatise Nifo sets forth what he calls the 'true position'. In fact, these passages are borrowed word for word from Albert the Great's *De natura et origine animae (On the Nature and Origin of the Soul)*. The same practice is continued in Book II, which concerns the felicity or 'state' (*status*) of the soul, a term found earlier in Albert and Jandun. While Nifo bases the 'true position' primarily on Albert the Great, it should be noted that Aquinas and Ficino play secondary roles. Nifo's remarks on individuation are basically Thomistic, and his emphasis on moral arguments for immortality seem to be inspired by his study of Ficino.

Some themes from Nifo's earlier writing reappear in *De intellectu*. He consistently attacks Jandun as misrepresenting Averroes' doctrines, especially by postulating that Averroes accepted intelligible species in his theory of intellectual cognition. He also rejects Aquinas' doctrine of a real distinction between the intellect and the will. But the most outstanding feature of *De intellectu* is Nifo's complete reversal of his position on Averroes. Although he spends much effort on determining the correct interpretation of Averroes' views on the soul and intellect, he now rejects Averroes as a true interpreter of Aristotle. He offers arguments against Averroes culled from Albert the Great, Thomas Aquinas and Marsilio Ficino, drawing especially on Aquinas' *De unitate intellectus contra Averroistas (On the Unity of the Intellect Against the Averroists)*, and on Ficino's *Theologia platonica (Platonic Theology)*. He states decisively that the immortality of the soul can be demonstrated, and he offers arguments drawn from Albert, Aquinas and Ficino. He attacks Alexander of Aphrodisias for denying immortality, and criticizes Vernia for proposing Alexander as a proponent of immortality. In like fashion, without mentioning him by name, he rejects Duns Scotus' view that immortality was a neutral topic because equally good arguments can be given for and against it (see Duns Scotus, J.).

A remarkable feature of *De intellectu* is Nifo's command of the thought of Plotinus, Alexander, Themistius and Simplicius, and his attempt to delineate their positions on the different topics that he treats. He also summarizes the contents of Siger of Brabant's *De intellectu*, thus serving as the primary source for knowledge of that now lost work (see Siger of Brabant).

4 Metaphysics

As early as his commentary on the *Destructio destructionum*, Nifo adopted a conceptual scheme of the hierarchy of being and a participation metaphysics that reflected his dependence on the thought of Aquinas (§9). God exists by virtue of his essence, and all other beings exist by virtue of their participation in God's existence. Moreover, this participation comes in degrees: higher creatures participate more fully in existence than do lower creatures, and so we get the hierarchically ordered system that has been called the Great Chain of Being. What is noteworthy about Nifo's position here is not so much the basic doctrines as his attribution of them to Averroes. In this attribution he was followed by others, such as Marcantonio Zimara.

Another of Nifo's early treatments of metaphysics is a commentary on Book XII of Aristotle's *Metaphysics*, published in 1505. Among the doctrines discussed by Nifo in his commentary are the movement of the heavenly bodies, the nature of divine cognition, the union of the human intellect with God, the infinity of God's power, and the relation of God and the Intelligences. Two constant themes are Aquinas' ability to interpret even corrupt texts correctly, and Averroes' misreadings, owing to his ignorance of Greek and consequent reliance on faulty translations. Nifo added that he was none the less forced to expound Averroes, since no one is considered an Aristotelian unless he is an Averroist. This early commentary was later incorporated into a commentary on the *Metaphysics* as a whole, published at Venice in 1547 after Nifo's death.

Nifo's own major work on metaphysics is his *Metaphysicarum disputationum dilucidarium (Clarification of Metaphysical Disputations)*, completed at Naples in 1510. One of the themes that he takes up is that of the transcendentals, being (*ens*), good (*bonum*), one (*unum*) and true (*verum*), so-called because they transcend Aristotle's ten categories. Nifo argues that no order can be established among the transcendentals, since they are all equally convertible with being. Nifo also notes that he has never read Aristotle calling being and one transcendentals (*transcendentia*) at all. Another topic of discussion was the distinction between existence (*esse*)

and essence (*essentia*) in created things. Nifo takes Aquinas to hold that in every caused thing existence and essence are really and simply distinct, principally on the grounds that that which participates is distinct from that in which it participates. Nifo argues that the Peripatetic position is that there can be no composition of essence and existence in the separate substances or in the heavenly bodies, but that Aquinas, as a Catholic though not as a natural philosopher, was forced to posit that essence and existence were distinct even in the Intelligences, since he considered them able not to exist. Nifo is quick to add that as a good Peripatetic, Aquinas rarely if ever departs from the thinking of Aristotle, and he adds that he himself rarely if ever departs from Aquinas.

EDWARD P. MAHONEY

List of works

For details of the publication of Nifo's Aristotle commentaries, see Lohr (1988).

Nifo, A. (1495, 1497) *Destructiones destructionum Averroys cum Augustini Niphi de Suessa expositione. Eiusdem Augustini quaestio de sensu agente (Agostino Nifo's Exposition of Averroes' Destructio destructionum. The Same Agostino's Question on the Agent Sense)*, Venice: Octavianus Scotus, 1497.(Nifo began his commentary on the medieval Latin version of Averroes' *Tahafut al-tahafut (Incoherence of the Incoherence)* in 1494 and finished it at Padua in 1497. He accepts Averroes' interpretation of Aristotle on the unity of the intellect and ascribes to him a participation metaphysics. His question on the agent sense, completed at Padua in 1495, was written to discredit Jandun's postulating such a faculty. God provides the spiritual factor needed for sensation to occur.)

Nifo, A. (1503) *Super tres libros De anima (On the Three Books On the Soul)*, Venice: Petrus de Quarengis. (Completed at Sessa in 1498 and published against Nifo's wishes. Although he knows Greek and cites Themistius and Simplicius, he considers Averroes to have correctly interpreted Aristotle on the unity of the intellect.)

Nifo, A. (1503) *Liber de intellectu (Treatise on the Intellect)*, Venice: Petrus de Quarengis.(Examination of such topics as immortality, unity of the intellect and cognitive union of humans to separate intellects and God. Rejects Averroes as reliable interpreter of Aristotle and gives arguments against unity of intellect and for personal immortality. True position on all major topics derived from Albert the Great.)

Nifo, A. (1505) *In duodecim metà tà physiká seu metaphysices Aristotelis et Averrois volumen (Volume on Book XII of the Metaphysics of Aristotle and Averroes)*, Venice: Alexander Calcedonius.(This is a commentary only on Book XII of Aristotle's *Metaphysics*. Nifo questions Averroes' interpretations.)

Nifo, A. (1508) *Aristotelis physicarum acroasum liber interprete atque expositore Eutyco Augustino Nypho (Aristotle's Book of Physical Discourses, Agostino Nifo the Translator and Expositor)*, Venice: Octavianus Scotus, 1508.(Completed in 1506 after only one year of work, the commentary reveals particular interest in Themistius and Aquinas.)

Nifo, A. (1510) *Metaphysicarum disputationum dilucidarium (Clarification of Metaphysical Disputations)*, Naples: Sigismundus Mayr Alemanus, 1511.(Begun at Salerno in 1507 and finished at Naples in 1510. Studies such topics as metaphysical participation, distinction of essence and existence, transcendentals, individuation, divine infinity and intuitive knowledge of God. The Venice 1559 edition of the *Dilucidarium* was reprinted by Minerva in 1967.)

Nifo, A. (1518) *De immortalitate animae libellus (Small Book on the Immortality of the Soul)*, Venice: Heirs of Octavianus Scotus.(Written against Pietro Pomponazzi's work *De immortalitate animae* and dedicated to Pope Leo X. Insists that Aristotle held to personal immortality. Offers arguments for immortality from different traditions: from Plato and Plotinus but also from Albert the Great and Aquinas. Human free choice shows the soul to be immaterial and immortal.)

Nifo, A. (1520) *Collectanea ac commentaria in libros de anima (Collected Remarks and Commentaries on the Books on the Soul)*, Venice: Heirs of Octavianus Scotus, 1522.(The *Collectanea* are Nifo's early commentary published in 1503; the *Commentaria* are a later commentary completed at Pisa in May 1520. Nifo at this point considers Averroes' explications of Aristotle worthless since he used bad translations. He therefore follows Themistius and Simplicius.)

Nifo, A. (1520) *Dialectica ludicra tyrunculis atque veteranis utillima (Playful Dialectics Useful for Beginners and Veterans)*, Florence: Heirs of Philippus Juncta.(An introduction to logic expressly opposed to recent logicians and claiming to be in harmony with real Aristotelians, the Greek commentators. Refers the reader to his commentary on the *Prior Analytics* (1524).)

Nifo, A. (1522) *De regnandi peritia (On the Practical Knowledge of Ruling)*, Naples: Aedes Dominae Catherine

de Silvestro, 1523; trans. S. Pernet-Beau, *Une réécriture du Prince de Machiavel: le De Regnandi Peritia de Agostino Nifo*, Paris: Université Paris X-Nanterre, 1987.(Completed at Sessa in 1522. Derivative from Machiavelli's *Il principe (The Prince)*.)

Nifo, A. (1524) *Prioristica commentaria (Commentary on the Prior Analytics)*, Naples: Evangelista Papiensis, 1528.(Completed at Salerno in 1524 and dedicated to Cajetan, that is, Thomas de Vio. Heavily dependent on John Philoponus and overall critical of Latin commentators with the exception of Aquinas.)

Nifo, A. (1529) *De pulchro et amore liber (On Beauty and Love)*, Rome: Antonius Bladus, 1531; trans. F. Sotas, *Sobre la belleza y el amor*, Seville: Secretariado de Publicaciones de la Universidad de Sevilla, 1990. (Completed at Niphanus, near Sessa, November 1529, this work attempts to construct a theory of beauty and love based on Aristotelian concepts and competing with the theory of Marsilio Ficino. Notable erotic element.)

Nifo, A. (1534) *Expositiones in omnes Aristotelis libros: De Historia animalium lib. IX; De Partibus animalium et earum causis lib. IV; ac De Generatione animalium lib. V (Expositions on All Aristotle's Books On Animals)*, Venice: Hieronymus Scotus, 1546.(Completed at Salerno in 1534 but published only after Nifo's death. Follows John Philoponus. Says Albert the Great 'babbled' and 'stuttered'.)

Nifo, A. (1535) *Aristotelis Stagiritae Topica inventio a magno Augustino Nipho Medice interpretata atque exposita (Aristotle's Invention, the Topics, Translated and Explained by Agostino Nifo Medici)*, Venice: Octavianus Scotus.(Completed at Niphanus in 1535. Considers it evil to attempt to explain Aristotle's works without knowing Greek and using the Greek commentators. Both Averroes and the Latins followed erroneous translations.)

Nifo, A. (1547) *Expositiones in Aristotelis libros metaphysices (Expositions on Aristotle's Metaphysics)*, Venice: Hieronymous Scotus.(A close textual study published posthumously. He cites his own Greek manuscripts and his *Dilucidarium* (1510), showing great esteem for Aquinas. Covers participation, analogy, infinity of God, divine Ideas and divine knowledge. The Venice 1559 edition of the *Expositiones* was reprinted by Minerva in 1967.)

Nihilism

As its name implies (from Latin nihil*, 'nothing'), philosophical nihilism is a philosophy of negation, rejection, or denial of some or all aspects of thought or life. Moral nihilism, for example, rejects any possibility of justifying or criticizing moral judgments, on grounds such as that morality is a cloak for egoistic self-seeking, and therefore a sham; that only descriptive claims can be rationally adjudicated and that moral (prescriptive) claims cannot be logically derived from descriptive ones; or that moral principles are nothing more than expressions of subjective choices, preferences or feelings of people who endorse them.*

Similarly, epistemological nihilism denies the possibility of justifying or criticizing claims to knowledge, because it assumes that a foundation of infallible, universal truths would be required for such assessments, and no such thing is available; because it views all claims to knowledge as entirely relative to historical epochs, cultural contexts or the vagaries of individual thought and experience, and therefore as ultimately arbitrary and incommensurable; because it sees all attempts at justification or criticism as useless, given centuries of unresolved disagreement about disputed basic beliefs even among the most intelligent thinkers; or because it notes that numerous widely accepted, unquestioned beliefs of the past are dismissed out of hand today and expects a similar fate in the future for many, if not all, of the most confident present beliefs.

Political nihilism calls for the complete destruction of existing political institutions, along with their supporting outlooks and social structures, but has no positive message of what should be put in their place. Cosmic nihilism regards nature as either wholly unintelligible and starkly indifferent to basic human concerns, or as knowable only in the sense of being amenable to scientific description and explanation. In either case, the cosmos is seen as giving no support to distinctively human aims or values, and it may even be regarded as actively hostile to human beings. Existential nihilism negates the meaning of human life, judging it to be irremediably pointless, futile and absurd. Cosmic and existential nihilism are the focus of this entry.

1 Historical background

Scattered uses of the term 'nihilism' can be found in philosophical, theological, political and literary writings of the late eighteenth and early nineteenth centuries in Europe. In that period, the term was sometimes used to refer to atheism and its alleged inability to provide support for knowledge and morality, or to impart purpose to human life; sometimes to any sort of uncommitted, sceptical or despairing outlook on existence; sometimes to philosophical idealists (especially proponents of the 'critical' philosophy of Immanuel Kant), on the basis that they negate any possibility of knowing or relating to objective, in-itself facts of the world by insisting that all experienced objects are constructions of the mind; and sometimes to socialists or anarchists, because their revolutionary philosophies were judged to be destructive of all political and social order. But the term first came into wide use in the period extending from the 1870s into the early years of the twentieth century, due largely to the influence of three writers: the Russian novelists Ivan Turgenev and Fëdor Dostoevskii, and the German philosopher Friedrich Nietzsche.

A character named Bazarov, in Turgenev's novel*Fathers and Sons* (1862), proclaims himself a nihilist and explains that nihilists 'act by virtue of what we recognize as beneficial'. What is most beneficial for the present, he continues, is 'negation, and we deny…everything'. Bazarov's nihilism quickly became famous in Russia and was warmly endorsed by certain revolutionary groups there in the 1860s, as well as being denounced by defenders of traditional beliefs and existing religious and political institutions. Dostoevskii was one such adamant defender, and his novel *The Possessed* (1871-2) gives a lurid portrayal of the lives of three members of a nihilist society, two of whom die by their own hand, the third at the hands of his comrades. Their existence is wretched and empty, the author implies, because they have lost faith in God and think that they must now arrogate to themselves God's absolute freedom. But theirs is an absurd freedom, without guidance or norms. It ravages their lives and brings them to pointless deaths. Dostoevskii propounded the theme of ruinous nihilism following inevitably from atheism through much of his literary career.

In notebooks composed between 1883 and 1888, parts of which were later published under the title *The Will to Power* (1901), Nietzsche announced 'the advent of nihilism' in European culture and ruminated at length on its character and causes (see Nietzsche, F. §7). There was one sense, he thought, in which nihilism could be attributed

to the declining influence of Christianity and loss of faith in God, for without God human life seemed deprived of purpose and value. But in another sense, Western civilization was now coming to realize that Christianity had stripped the world of immanent meaning - thus containing in itself the seeds of the most thoroughgoing nihilism - by insisting on the necessity for a transcendent ground of truths and values, and focusing most of its attention on attainment of a paradise beyond the grave where the trials and sorrows of earthly existence would be redeemed.

The task to which Nietzsche devoted much of his writing, therefore, was twofold. The first part was to do relentless battle with Christianity and lay bare what he regarded as its implicit nihilism, thus freeing European culture from its spell. The second was to find some way to move beyond the nihilistic desolation that Nietzsche's character Zarathustra foresees in *Thus Spoke Zarathustra* (1883-85), following hard on the heels of his startling discovery of 'the death of God'. Nietzsche condemned as 'passive nihilism' the despairing resignation with which Arthur Schopenhauer and other radical pessimists responded to the looming crisis of the West. He sought to develop a vision of an 'active nihilism' that would fully acknowledge important findings of epistemological, moral and cosmic nihilism, but convert them into stepping stones to a new affirmation of life.

2 Cosmic nihilism

The absolute form of cosmic nihilism denies to the universe any sort of intelligibility or meaning. It is blank and featureless, giving no response to the age-old human search for understanding and no support to distinctively human aims, aspirations or purposes. All attempts to comprehend the world, including those of the various natural sciences, are doomed to failure. Whatever meanings or values we may think we have found in it stem from unconscious projections of our own suppositions and wishes, because it contains no knowable traits, principles or patterns that would enable it to be understood, and it is utterly lacking in discernible value. This total alienation of human understanding and need from the surrounding universe is asserted by the German thinker Max Stirner, when he states that the world 'cannot be regarded as a comprehensive structure of objective meanings' but must rather be seen 'as a metaphysical chaos'. This conclusion follows from Stirner's radical nominalism, which views the world as a loose aggregation of unique, self-contained particulars which exhibit no intelligible relations to one another. As for values, Stirner's nominalism led him to the view that we must fend for ourselves; individuals are left isolated in a chaotic world to find as much private enjoyment and achieve as much power over others as they can.

A similar bleak view of the cosmos is taken by Antoine Roquentin, a character in Jean-Paul Sartre's novel *Nausea* (1938). The fundamental discovery he makes is that 'the world of explanations and reasons is not the world of existence'. An uncrossable chasm yawns between the concepts, descriptions, explanations and valuations of human beings on the one hand, and the world on the other. From the perspective of his recurring experiences of 'nausea,' Roquentin perceives the world to be like a thick paste or oozing slime, without character or distinction, and impenetrable to the mind (see Sartre, J.-P. §4). In much the same fashion, Albert Camus speaks in *The Myth of Sisyphus* (1942) of the world as 'dense' and 'strange', a 'vast irrational' wholly unresponsive to human attempts to find a home within it or to comprehend its meaning. Schopenhauer, in the early nineteenth century, went even further than these thinkers in denuding the world of value. He argues in *The World as Will and Idea* (1818) that the cosmos is steered by a blind impulse or energy that is not merely oblivious to matters of good and evil but actively hostile to human beings, generating a horrible preponderance of sufferings over pleasures and disappointments over satisfactions.

The relative form of cosmic nihilism sees the world as fully open to scientific understanding but denies to it any normative significance. The real universe, in this outlook, is the purely descriptive one being brought steadily into view by the natural sciences, a universe of factual principles and laws that gives no place or support to the moral, aesthetic and religious concerns that preoccupy human life. The French biochemist Jacques Monod develops this idea in *Chance and Necessity* (1970), where he identifies 'the essential message of science' as an objective portrayal of the cosmos that 'outrages values' by making them 'seem to melt into the world's uncaring emptiness'. Humans must somehow reconcile themselves to living 'on the boundary of an alien world' just as indifferent to their hopes as it is to their sufferings or crimes.

3 Existential nihilism

Existential nihilists contend that human existence has no purpose, value, or justification. There is no reason to live,

and yet we persist in living. The human situation is therefore absurd. The philosophical position of existential nihilism is not just that this or that person may fail to find meaning in life; it is rather that a genuinely meaningful life is impossible. In the face of this conclusion, Schopenhauer counsels us to quench the flame of affirmation and desire, to resign ourselves to the span of our days without hope of respite and calmly await an annihilating death, the last sure sign of the utter futility of our existence. Sartre too hammers at the absurdity of existence but counsels us in *Being and Nothingness* (1943) to invent meanings for our lives through sheer acts of freedom, creating those meanings - in the manner of the God of traditional religion - out of nothing. Camus, in *The Myth of Sisyphus*, finds the absurdity of the human situation to lie in our restless, futile search for comprehensive meaning in a universe that has no discoverable significance or value. He advises us not to commit suicide when we realize that our lives have no point - that would be the coward's way out. Instead, we should heroically rebel against the abyss of meaninglessness and in that very act of defiance find some semblance of a reason for being (see Existentialism).

A relentless, uncompromising exponent of existential nihilism is the Romanian philosopher E.M. Cioran. In *A Short History of Decay* (1949), he notes that most of us strive throughout our lives to ' keep deep down inside a certitude superior to all the others: life has no meaning, it *cannot* have any such thing'. Civilizations, philosophies, religions - all are ways of masking this inescapable truth, of seeking to divert our attention from its shattering impact. How, then, can we cope with it? As against Schopenhauer, Cioran insists that we cannot escape torturing ourselves with awareness of the 'disease', 'shame' and 'curse' of our existence. Our probing, questioning minds give us no peace; only those living in shallowness and illusion can avoid their constant torture. As against Camus, Cioran argues that we all *should* commit suicide: this is the only consistent way of dealing with the absurdity of our lives. But we foolishly compound the absurdity by refusing, in our cowardice, to do away with ourselves. As against Sartre, Cioran contends that ' the intoxication of freedom is only a shudder within a fatality, the form of [our]…fate being no less regulated than that of a sonnet or a star'. For beings born only to experience the crushing inevitabilities of disappointment, suffering and death, a freedom thrown defiantly against the void can give no respite. From 'spermatozoon to sepulchre' we are pawns of a taunting fate that arbitrarily selects some for good fortune and others for bad. Each life is a useless 'hyphen' between birth and death. Human history, as evolutionary biology and scientific cosmology show, is that of one more organic species doomed, like all the rest, to extinction, and of a mere fleeting breath in the universe's onrush to entropic death. Analogous to Sartre's descriptions of 'nausea' is Cioran's acknowledgement of a sickening 'disgust' welling up from such recognitions: ' that *negative* superfluity which spares nothing…[and] shows us the inanity of life'.

4 Critical comment

That the threat of nihilism is still very much with us is indicated by Loyal Rue's book, *By the Grace of Guile: The Role of Deception in Natural History and Human Affairs* (1994). Rue states that he is convinced of two things: that nihilism is true and that human beings cannot live with its truth. Rue does not so much systematically argue for nihilism as confess himself to be firmly in its grasp. The solution he proposes is that of a 'Noble Lie', that is, a programme of mythical re-enchantment of the universe which will deceive people into believing that it and they both have significance, even though neither has. This desperate and implausible strategy shows the continuing power of nihilism, here regarded as a kind of foregone conclusion.

Martin Heidegger, a prominent critic of nihilism in its various forms, attributes what he regards as the nihilistic malaise of the West - astutely predicted by Nietzsche - to an inherited tangle of epistemological and metaphysical misconceptions that have led to a disastrous 'forgetfulness of being'. Only if we go back to the philosophical roots of the Western world, in the profound reflections of the Presocratic philosophers that Heidegger considers to have been distorted by Plato and Aristotle (these distortions having plagued us ever since), can we come to understand how the objectifying, separating, controlling and ego-centred modes of present thought and experience have led us to nihilism. Heidegger's solution lies in our learning radically to 're-vision' reality, to become receptive to the healing presence of being that shines through all beings and binds us to one another and to the world (Heidegger 1953). A powerful explication and defence of Heidegger's general approach to nihilism is contained in Levin (1988).

Arguments for cosmic and existential nihilism, like those for the other forms of nihilism, are complex and varied. Detailed analysis and criticism of some of them can be found in Crosby (1988), which probes beneath the arguments themselves to the crucial assumptions that underlie them, many of which stem from the legacy of

seventeenth- and eighteenth-century Western thought (some examples of these assumptions are given below). The book concludes that, while philosophical nihilism has important lessons to teach us, it is ultimately a distorted and one-sided view of ourselves and the experienced world, one that turns on highly questionable assumptions.

Many such assumptions lie behind some of the arguments put forward in support of cosmic nihilism. Proponents believe that if claims about the universe cannot be convincingly shown to correspond to what it is in and of itself, apart from human experience and conceptualization, then we cannot be said to have any significant understanding of the universe. Additionally, they sometimes think that the presence of purposive activity in the universe (for example, in human beings and other animals on earth) is not enough to give it meaning - for this there must be a discernible purpose of the universe *as a whole*. Such thinkers often demand that the universe must have a ‘human face’, have its ground in a personal divine Being and be centred on humans and their distinctive concerns. Others rely on natural science as the final arbiter of the nature of nature and assume that, since science discovers no values in nature but only descriptive facts and relations, nature is devoid of value. Some suppose that if, as natural science claims, the universe had an accidental beginning (the Big Bang) and will eventually come to an absolute end (its inevitable entropic death, assuming that the universe is a closed system) then it follows that the universe can have no meaning.

Similarly, proponents of existential nihilism use arguments which are informed by a number of disputable assumptions. They may believe that a life which ends in annihilating death cannot be said to have meaning, or that there is too much suffering, or constant threat of suffering, in human life for it to be meaningful. They sometimes conceive of time as a series of disconnected moments, and hence believe that our lives in time can have no cumulative pattern or significance. Often they assume that meaningful values, including the existential ones that relate to the course and direction of our lives, must be conferred on us from on high and thus have a transcendent source and sanction. Others believe that values, including existential ones, can have no significance or weight unless they are absolute, unconditioned, timeless and universal, or that our lives are meaningless if they are the outcome of a process of biological evolution, guided by the principle of natural selection that is non-purposive and non-designed. That human beings are locked in their individual subjectivities and doomed to invent arbitrary meanings for themselves, with no objective rules or standards, is yet another assumption that often underlies the existential nihilist’s argument.

All these suppositions are open to serious criticism. When they are brought under careful scrutiny, arguments that depend on them lose much of their force. Still, there is considerable truth about the world and the human condition that nihilistic arguments in general can bring home to us. Reflection on such arguments can sharpen our philosophical vision in fundamental and positive ways.

Stirner, M. (1845) *The Ego and His Own*, trans. J. Carroll, New York: Harper & Row, 1971. (Presents an ego-centred nominalism implying moral, epistemological and cosmic nihilism; see §2 above; relatively easy.)

Tillich, P. (1953) *The Courage to Be*, New Haven, CT: Yale University Press.(Draws on the ideas of Heidegger, among others, to discover resources for coping with the threats of 'non-being' in the forms of fate and death, guilt and moral self-condemnation, emptiness and meaninglessness. Finds 'the courage to be' in the 'God above God,' that is, the power of 'being-itself'; moderately difficult.)

Turgenev, I. (1862) *Fathers and Sons*, trans. M.R. Katz, New York: W.W. Norton, 1994.(A novel about the seductions of nihilism for youths in nineteenth-century Russia; see §1 above; relatively easy.)

Nihilism, Russian

The term 'Nihilist', although it was first used in Russian as early as 1829, only acquired its present significance in Turgenev's novel Ottsy i deti (Fathers and Sons) (1862), where it is applied to the central character, Bazarov. Thereafter Nihilism quickly became the subject of polemical debate in the journal press and in works of literature. The Nihilists were the generation of young, radical, non-gentry intellectuals who espoused a thoroughgoing materialism, positivism and scientism. The major theorists of Russian Nihilism were Nikolai Chernyshevskii and Dmitrii Pisarev, although their authority and influence extended well beyond the realm of theory. Nihilism was a broad social and cultural movement as well as a doctrine.

Russian Nihilism negated not the normative significance of the world or the general meaning of human existence, but rather a particular social, political and aesthetic order. Despite their name, the Russian Nihilists did hold beliefs - most notably in themselves and in the power of their doctrine to effect social change. It is, however, the vagueness of their positive programmes that distinguishes the Nihilists from the revolutionary socialists who followed them. Russian Nihilism is perhaps best regarded as the intellectual pool of the period 1855-66 out of which later radical movements emerged; it held the potential for both Jacobinism and anarchism.

1 The Nihilist movement: materialism as way of life

Russian Nihilism is a phenomenon of cultural history just as much as a current in Russian thought. Educated Russians in the nineteenth century had a marked propensity not only to reflect on but also to live by ideas, and nowhere is this more evident than in the radical movement of the 1860s. In the decade following the death of Tsar Nicholas I the new class of educated commoners (the *raznochintsy*) felt the delayed intellectual impact of materialism, which they converted into an all-consuming worldview. Characteristic of the Nihilists was a rejection of all authorities other than materialism itself. In *Ottsy i deti (Fathers and Sons)* (1862) a Nihilist is defined as someone who 'does not bow down before any authorities, who does not take a single principle on faith'. Turgenev's Bazarov trusts only the exercise of his own rational faculties in the spirit of scientific inquiry.

The leading lights of Russian Nihilism were Nikolai Chernyshevskii and Dmitrii Pisarev, whose articles appeared in *Sovremennik (The Contemporary)* and *Russkoe slovo (The Russian Word)* (both of these radical journals were closed for good after the attempted assassination of the Tsar in 1866). Chernyshevskii wrote prolifically, but by far his most influential work was *Chto delat' (What Is To Be Done?)* (1863), which became the catechism of the Nihilist 'new men'.

This novel offered them less a utopian vision than a practical programme of social action and a code of moral conduct. The main characters embodied the Nihilist ideals of equality, personal liberation and 'rational egoism'. The novel's artlessness, moreover, provided an excellent illustration of the new 'realist' aesthetics propounded by the Nihilists. Among Pisarev's most famous essays is 'Bazarov' (1862), a review of *Fathers and Sons* where he accepted Turgenev's depiction of the younger generation and thereby sparked an acrimonious debate within the Nihilist camp. Pisarev argued that Bazarov had enormous significance as a representative of the new worldview, and drew particular attention to his rejection of abstraction and his commitment to immediate and concrete action. Bazarov, unlike the earlier socially alienated 'superfluous men' of Russian literature, had both the will to act and the knowledge to act effectively. The Nihilist movement belonged to the young. It contained an element of protest not only against the existing order but also against the older generation, the intellectual 'fathers' who had been brought up on German Idealism rather than Feuerbach. The Nihilists gave short shrift to anything that smacked of sentimentality or romanticism. Rather like protesting youth in the twentieth century, the Nihilists cultivated their own style of dress and behaviour, which is particularly evident in contemporary descriptions of women radicals (*nigilistki*). One conservative newspaper noted that they were:

> usually very plain, exceedingly ungracious, so that they have no need to cultivate curt, awkward manners; they dress with no taste and in impossibly filthy fashion, rarely wash their hands, never clean their nails, often wear glasses, always cut their hair, and sometimes even shave it off.
>
> (Moser 1964: 44)

The 'woman question' did in fact occupy a prominent place in Nihilist social thought. In *What Is To Be Done?*

Chernyshevskii affirmed the importance of women’s personal liberation and sexual freedom. The Nihilist striving for women’s emancipation was reflected in the phenomenon of fictitious marriages: in the 1860s a young woman wanting to gain independence from her family might search out a young man willing to go through the nuptial rites with her, and would then be free to join a sewing cooperative or disappear abroad to study.

For the young Nihilists materialism was less a philosophical doctrine than an article of faith and a guide to action: it carried with it a new ethic of scientific inquiry, personal liberation and social activism. The Nihilists were convinced that the methods of the natural sciences would bring benefits if applied to the study of man, art and society. They asserted the prime social value of work and advocated the introduction of rational forms of social cooperation, most notably in the communal movement. But perhaps most importantly of all, they were blessed with boundless faith in themselves and their ideas. As Pisarev wrote in his essay ‘Mysliashchii proletariat’ (‘The Thinking Proletariat’) (1865), the new man ‘believes in his reason and in his reason alone’. For the Nihilist the intellectual emancipation of the individual came before social emancipation. Enlightenment was to be spread throughout society by the actions of an elite group of ‘new men’.

The contemporary observer Nikolai Strakhov suggested that ‘Nihilism itself hardly exists, although there is no denying the fact that Nihilists do’. The Nihilists undoubtedly did form a significant social movement, but their activities were underpinned by a materialist doctrine. The philosophical content of Nihilism will be examined in greater detail in the next section.

2 Nihilist doctrine

The 1860s were once described by Trotsky as ‘a brief eighteenth century’ in Russian thought. The Nihilist thinkers sought to assimilate and resynthesize the main trends in Western materialism and positivism. As usual in Russia, imported ideas were treated selectively and deployed in quite distinctive intellectual formations.

The best-known and most scandalous statements of the Nihilist position came in the field of aesthetics. In Russia from the 1840s onwards literature could be both the instrument and the subject of social, philosophical and political debate: for the Nihilists too it was both a target and a weapon. Chernyshevskii’s master’s thesis, ‘Esteticheskie otnosheniia iskusstva k deistvitel’nosti’ (‘The Aesthetic Relations of Art to Reality’) (1855), identifies the main criteria of artistic value in the new ‘realist’ aesthetic. Chernyshevskii counters idealism in aesthetics, and argues that art is always aesthetically inferior to reality. Art’s worth is thus defined by its faithfulness to reality. The artist, however, does more than provide naturalistic snapshots of life: the work of art contains not only accurate depiction, but also explanation and assessment of reality. Chernyshevskii’s views helped to spawn a new school of civic-minded criticism which assessed works of literature for the faithfulness and ‘typicality’ of their depiction of contemporary Russian society. The most brilliant representative of this school was Chernyshevskii’s friend and disciple Nikolai Dobroliubov, whose essays included an impassioned sociological reading of Goncharov’s *Oblomov* (this novel contained perhaps the most celebrated Russian depiction of social superfluousness). Pisarev summed up well the demands the Nihilists made of the artist: ‘The true, "useful" poet must know and understand everything that at a given moment interests the best, the most intelligent, and the most enlightened representatives of his age and nation’. Realist aesthetics, in its concept of the ‘typical’, did not in fact manage to part entirely with the Hegelian notion of the ideal: art was expected not simply to depict reality, but to single out the ‘most real’ part of reality.

For the Russian Nihilists, reality was the world of nineteenth-century science. Taking its lead from the contemporary German materialists Büchner, Vogt and Moleschott, their worldview left no room for anything other than force and matter. In his essay, ‘Antropologicheskii printsip v filosofii’ (‘The Anthropological Principle in Philosophy’) (1860), Chernyshevskii mounts an assault on philosophical dualism and abstraction, arguing that materialism proves the ‘unity of the human organism’. He concedes the distinction between ‘moral’ and ‘material’ phenomena, but maintains that it is one of degree rather than of kind. Chernyshevskii’s ‘anthropological principle’ was intended to prove that the methods of the natural sciences were applicable to the study of man. As these methods became more sophisticated, the moral sciences would inevitably attain complete understanding of the causes of human behaviour.

To his scientism and determinism Chernyshevskii added an ethics based on ‘rational egoism’. ‘Good’ and ‘bad’, he argues, are not inherent in human nature. Man always acts in his own interests and does what is ‘useful’ for

him. Good is thus defined as 'the superlative of utility'. Chernyshevskii's theory of rational self-interest is underpinned by the optimistic assumption that the interests of society and those of the individual naturally coincide. If individuals, acting as always in their own interests, commit 'bad' deeds, then it is the social order that must be at fault. Chernyshevskii's determinism was thus profoundly polemical. In his essay 'The Thinking Proletariat' (1865) Pisarev makes the similar argument that selfishness is useful if it is allowed to find a productive outlet, and that work is the best way of harmonizing the interests of all members of a society. Idleness and exploitation, on the other hand, lead man's natural selfishness to take destructive forms. In the Nihilist 'new men' individual qualities and the general interest are inseparable: 'goodness and truth, honesty and knowledge, character and reason are identical'.

Largely because of this faith in the natural state of harmony between the individual and society, the Nihilists tended to leave their social programmes vague. They were certainly committed to a form of secular socialist society with guaranteed rights for the individual, but their main contribution to social debate was their rejection of existing authority. The Nihilists were, however, unswerving in their commitment to social change through the spread of enlightenment and in particular the natural sciences. They believed that if true 'understanding' was brought to people through the dissemination of knowledge, social progress would inevitably follow. Pisarev laid particular emphasis on the role of education in social change. In his essay 'The Realists' (1864) he argues that science must find its way into the everyday life of the common people if they are to break out of the vicious circle of poverty and ignorance. With a characteristically Russian faith in the power of ideas, he asserts that the wise investment of 'intellectual capital' can 'diminish the quantity of human pains'.

Nirvāṇa

The aim of the spiritual life was already described as nirvāṇa *before the rise of Buddhism around the fifth century BC, but it is in the Buddhist context that it is most well known. In earlier Buddhist works and in popular usage to the present day it refers to the goal of Buddhist discipline, reached by systematic training in morality, meditation and intellect. That goal consists of the final removal of the disturbing mental elements which obstruct a peaceful and clear state of mind, together with a state of awakening from the mental sleep which they induce. Such an awakening (often referred to in English as 'enlightenment') enables a clear perception of fundamental truths, the understanding of which is essential to mental freedom. Later, the term was often applied more narrowly to a specific aspect of the awakened condition - that aspect of this experience which was considered to be unchanging, that is, an element which is not the product of either mental construction in particular, or of causes and conditions in general.*

1 Origins and etymology of the word *nirvāṇa*

Nirvāṇa (or *nibbāna* in the Pāli language) means literally 'blowing out' or 'quenching'. However, since the term is probably pre-Buddhist, its etymology is not necessarily conclusive for determining its exact meaning as the highest goal of early Buddhism. In fact, many Buddhists have traditionally preferred to explain it as absence of the weaving (*vāna*) activity. Here weaving is a metaphorical description of the mind's manner of operation when distorted by ignorance of the true nature of things and by craving for possessions and states of being. It is probably not accidental that such a definition does not tell us what exactly *nirvāṇa* is. Buddhists have generally avoided any verbal description of their goal and have tended to doubt whether it is possible to describe it.

The earliest Buddhist texts seem to use the word *nirvāṇa* to designate the final end (*accantaniṭṭhā*) of the path taught by the Buddha. As such it is by definition supreme happiness and ultimate peace. Probably they shared this with other religious-philosophical schools of the period. The same texts generally go to great lengths to avoid discussing what happens to the attainer of this goal after death. The Buddha is presented as 'not having declared' that such a one exists after death or does not exist then. Nor did he declare that both of these were the case. Even a denial of both possibilities was ruled out as an option. Indeed, concern with the nature of that goal of happiness and ultimate peace is presented as unhelpful to the task of achieving it. The simile of the man injured by a poisoned arrow is commonly cited in this context: in the immediate situation he should focus upon obtaining medical treatment rather than be concerned with specific details of the arrow, poison or archer. Similarly the urgency of attaining *nirvāṇa* is such that it is better not to be overconcerned with details of its nature and consequences.

From the origins of the word itself it is possible to assess the earlier position which is being reacted to here. *Nirvāṇa* derives from the root 'to blow' and means the blowing out or quenching of a lamp flame or a fire. In one use it is the fires of passions, such as greed and hate, which are put out by the enlightened sage. In another usage, applicable to the time of death, the flame of the lamp covers all types of ordinary human activity. These cease at the death of the enlightened saint, like the flame of a lamp. In pre-Buddhist usage this would probably have been understood as meaning that the fire had returned to the latent or potential state from which it arose in the first place. Contrary to its modern ascription, the metaphor would not have had connotations of annihilation. The Buddha himself seems to have resisted this kind of understanding, perhaps because it was too closely associated with the pantheistic self of the Upaniṣads, or the life-monad of the Jains and others (see Jaina philosophy). Rather, the Buddhist texts tend to suggest that language is inapplicable to the case since words are in the last analysis derived from sensory experience, which is taken to include memory and imagination.

2 Earlier accounts

Most mentions of *nirvāṇa* refer to it as the goal, or as supreme happiness with many synonyms which make clear that it is conceived as the ultimate security, purity and peace. A few of the early texts, mostly preserved in Pāli or Chinese translations, provide a little more information. Someone who experiences *nirvāṇa* is explicitly declared to be conscious, but not conscious of 'anything which the mind has seen, heard, sensed, felt, obtained, sought or explored' (*Anguttara Nikāya (The Book of Gradual Sayings)* IV 320; 353-8). This experience is differentiated from various kinds of meditative attainment.

Later a clear distinction between *nirvāṇa* attained in life and *nirvāṇa* entered into at the point of death begins to develop. The term *parinirvāṇa* is often used for the latter although it does not acquire this meaning until a later date - in the earliest sources it is simply an alternative to *nirvāṇa*. (Strictly, *nirvāṇa* is the state of release; *parinirvāṇa* is the act of attaining release.) However, relatively early sources (although not the very oldest) do contain the important simile of the ocean which shows no sign of filling or diminishing no matter how much water is poured into it by streams or rainfall. Similarly, even if many enter *parinirvāṇa* by means of the element of *nirvāṇa* without any remaining 'clinging', the element of *nirvāṇa* shows no sign of filling or diminishing. Here 'clinging' is a technical term referring to the appropriation or identification which occurs as a result of desire. Since ordinary human existence and mental process are understood as the result of such appropriation, there can be no continuation in the familiar conditions of existence once it has ceased. The point of the simile is no doubt to emphasize that *nirvāṇa* transcends normal rules.

3 European understanding of the term

The *Oxford English Dictionary* (first edition) defines *nirvāṇa* thus: 'In Buddhist theology, the extinction of individual existence and absorption into the supreme spirit, or the extinction of all desires and passions and attainment of perfect beatitude'. Although versions of this definition have been widely used, it confuses the Buddhist with Jain and Hindu understandings of the term (see Karma and rebirth, Indian conceptions of). Such descriptions of *nirvāṇa* are rather old in European thought. By the seventeenth century the French ambassador to the Siamese court, Simon de La Loubère referred to Portuguese authors as having translated a closely related Siamese term as 'it is annihilated' and 'it has become a God'. He rightly indicated that in the opinion of the Siamese: 'this is not a real Annihilation, nor an Acquisition of any divine Nature'. In fact, La Loubère translated *nirvāṇa* as 'disappearance', meaning disappearance from the world of birth and death. This is a very accurate understanding of the term and cannot be bettered today.

However, little attention was paid to La Loubère's more reliable account of the term, and the views he corrected remained current. Part of the reason for this was the tendency, especially in the seventeenth and eighteenth centuries, but still current in some circles, to understand Buddhism as a form of paganism and then to apply to it the critique which the Church Fathers directed against pagan philosophy. While there are some similarities between the two areas, such as the belief in reincarnation characteristic of some forms of classical philosophy, overall this is inappropriate.

4 Schools of mainstream Buddhism

By the time of the development of the first forms of organized Buddhist exegesis in the third or fourth centuries BC slightly more systematic ideas were found (see Buddhist philosophy, Indian). *Nirvāṇa* as the element 'without any remaining clinging' was contrasted with the element 'with remaining clinging' (*saupādisesa*). This latter perception of *nirvāṇa* connoted the stages of partial enlightenment known as 'entering the stream'. As earlier texts most often referred to *nirvāṇa* 'without any remaining clinging' in the context of the Buddha's death, it began to be assumed that if what was attained at the death of the saint was the element of *nirvāṇa* "without any remaining clinging', then there must be a corresponding element which was achieved at enlightenment. Henceforth, the element of *nirvāṇa* 'with remaining clinging' regularly referred to the achievement of enlightenment, normally envisaged as followed by a life of compassionate teaching activity. As a result of a later mistranslation or misunderstanding, the word translated as 'clinging' is often replaced by a word which may refer to 'possessions' (*saupadhiśeṣa*) and taken as referring to the mind and body as possessions appropriated during the process of rebirth. Alternatively, both *saupādisesa* and *saupadhiśeṣa* could derive from **upādhisesa* and **upātisesa* respectively, meaning 'small remainder'. Thus, originally the meaning of the terms connoting 'clinging' could have been a reference to the small number of defilements remaining after 'entering the stream'.

Older sources are reticent on the subject of *nirvāṇa*. However, the same is not quite true of the canonical *abhidhamma* literature which took form between the second and fourth centuries BC. A characteristic feature of this literature is the analysis of mind and body in terms of a changing process of interacting and multiple events. These were referred to as *dhammas*, that is, particular truths as opposed to truth in general. (Earlier the word was used for all objects of mental awareness other than sense objects themselves.) The *abhidhamma* texts compiled open-ended lists of these events and tried to analyse which events occurred in which mental states. In this analysis they

included *nirvāṇa* which they explained as differing from all other events in that it was not categorizable in spatial or temporal terms. At this stage there does not seem to have been any controversy as to its fundamental nature, nor was it conceived as mere absence: '*Nibbāna* exists; it does not change its nature. *Nibbāna* is permanent, constant, eternal, not subject to change' (*Kathāvatthu (Points of Controversy)* 122).

It is probable that the main concern of the *abhidhamma* texts was with the experience of *nirvāṇa* in life in terms of awakening or enlightenment. In that context *nirvāṇa* would be understood as the object or support for the enlightened mind, itself a composite characterized by the repeated presence of such events as faith and wisdom. Like the texts which preceded them, the works of this period did not attempt to comment upon the fate of the enlightened saint after death. No doubt the tradition of the undeclared questions was still too firmly established to allow this.

5 In the Mahāyāna systems

New tendencies in Indian religion, developing over some time, led to the formation of a new kind of Buddhism in the period AD 100-300: the Mahāyāna or 'great vehicle'. Attracting only minor interest in the beginning, the new movement gradually became increasingly influential. Devotional elements were strong in this school which arose essentially from an elaboration of the idealized biography of the Buddha and an extension of that into an ideal for all. An important feature was the prolongation of the path to enlightenment in order to enable the development of the superior qualities seen as necessary to achieve Buddhahood and work more effectively for the benefit of others. A side effect of this shift in focus was that *nirvāṇa* receded somewhat into the background, although in some subsequent schools of Mahāyāna Buddhism, such as Chan/Zen or Tantra, it was ultimately to return to the foreground as something attainable in this life.

New schools of thought developed within the overall Mahāyāna with particular perspectives. Probably the oldest of these was the Madhyamaka (see Buddhism, Mādhyamika: India and Tibet). This laid stress on the idea that there was no difference between *nirvāṇa* and existence in the round of rebirths (*saṃsāra*). They seem to have meant by this that *nirvāṇa* is simply a name for ordinary existence with ignorance removed. In other words it is not to be viewed as an entity existing somewhere else. It is rather a transformation of normal experience.

Some later Mahāyāna writings placed an emphasis on '*nirvāṇa* without foundation' as part of the path to the highest goal. This means that true enlightenment involves neither acceptance nor rejection of birth and death. More remarkably, it implies neither accepting nor rejecting *nirvāṇa* itself, but instead encouraging minds to be free of dependency upon or need for any objects at all, whether those objects are internal or external.

6 Synonyms for *nirvāṇa*

A common error in examining a concept such as *nirvāṇa* is to focus too much on the exact denotation of the term at the expense of its wider associations and context, not taking into account the number of synonyms frequently used to describe it. In a practical, experiential context it is referred to as 'freedom' or 'awakening'; 'peace' or 'bliss'. In each case the implication is that it is this in the ultimate possible degree. Words which imply safety or complete protection are commonly used in relation to it, as are words which imply permanence, unchangingness or unendingness. These latter denotations are close to the general terms used in Indian religions to describe the highest goal of the spiritual life. Many such words are regularly used to describe *nirvāṇa*. So it is liberation (*mokkha*/*mokṣa*), wholeness (*kevala*/*kaivalya*), truth and the like; it is the deathless and the imperishable. Many of these terms are given a specific Buddhist sense, but their general connotation in the world at large should not be neglected. A specific example might be that *nirvāṇa* is the *amṛta*, or the deathless, but it is important that this refers to the nectar which confers immortality upon the gods. In the Buddhist context it refers to a condition in which there is no death, although it is clearly intended to have the positive associations of Indian myth.

Nishi Amane (1829-97)

Among the campaigners for Japanese enlightenment in the early Meiji era, Nishi Amane was prominent for his philosophical achievements. He introduced European philosophy into Japan, especially the positivism of Auguste Comte and the utilitarianism of John Stuart Mill. The academic philosophy of modern Japan owes its origins to him.

The son of a court physician of the Tsuwano fief, Nishi was ordered by his lord to learn neo-Confucianism. Quite unsatisfied by this old-fashioned doctrine, he became aware of the necessity for studying Western science and fled the fief. In 1857 he was employed at the Foreign Books Research Institute by the Tokugawa government, and in 1862 he was sent by the government to Leiden in Holland on a mission to study the European social sciences. He studied law, statistics and economics formally under S. Vissering, but he also attended lectures by C.W. Opzoomer, then the leading historian of philosophy in Holland. Opzoomer introduced him to the works of Auguste Comte and J.S. Mill.

Having returned home in 1865, Nishi continued to work for the Tokugawa government and, after the Restoration, was appointed to the Military Department of the Meiji government in 1870. He contributed much to the establishment of the modern Japanese military during his bureaucratic career, while as a private individual he introduced European philosophy and social sciences through his writing and teaching. From 1870 onwards he ran a private school called the Ikueisha. In 1873 he took part in the inauguration of the Meirokusha (the Meiji Six Society), an active scholarly society, and promoted the campaign for the enlightenment of the Japanese people.

Nishi's philosophical writings were motivated by criticism of Confucianism and praise for Western scientific thinking. In *Hyakuichi-shinron (New Theory of the Hundred and One)*, published in 1874, he stressed the distinctions between morality and law and between human and natural principles. Embracing a dualistic attitude, he declared himself against the monism of the Confucians, especially the neo-Confucian world view. In *Jinsei-sanposetsu (Theory of the Three Human Treasures)*, he enumerated health, knowledge and wealth as the *sine qua non* for happiness. He opposed these to the feudalistic values of docility, naivety, humility, deference, unselfishness and freedom from avarice. Thus he replaced the group-oriented morality with a utilitarian-individualistic one. In *Hyakugaku-renkan (Links of All Sciences)*, which consists of drafts of his lectures at Ikueisha, he showed the classification and harmony of all disciplines, assigning the pivotal position to philosophy. He also explained Comte's theory of three stages and Mill's method of induction. Moreover, he published the first Japanese textbook on formal logic, *Chichi-keimo (Logic and Enlightenment)* in 1874, and a translation of Mill's *Utilitarianism* in 1877. As Thomas R.H. Havens states:

> Because Nishi's contributions… were the transmission of European ideologies and the invention of new academic terminology, rather than original thought systems of his own, Nishi did not found any new school of Japanese philosophy. However, his influence is to be found in the works of…various important philosophers in Meiji era.

Nishida Kitarō (1870-1945)

Considered Japan's first original modern philosopher, Nishida not only transmitted Western philosophical problems to his contemporaries but also used Buddhist philosophy and his own methods to subvert the basis of traditional dichotomies and propose novel integrations. His developmental philosophy began with the notion of unitary or pure experience before the split between subject and object. It developed to challenge other traditional opposites such as intuition and reflection, fact and value, art and morality, individual and universal, and relative and absolute. In its organic development, Nishida's philosophy reacted to critiques that it neglected the social dimension with political essays that sometimes aligned it with Japanese imperialism. It culminated in the 'logic of place', a form of thinking that would do justice to the contradictory world of human actions.

While a teacher in his twenties and thirties, Nishida fervently practiced Zen Buddhism under masters of the Rinzai lineage. After the publication in 1911 of his groundbreaking work *Zen no kenkyū (An Inquiry Into the Good)*, he held professorships at Kyoto Imperial University until his retirement in 1929. Nishida produced numerous essays, developing a logic of consciousness and, from the 1930s, a philosophy of history and culture. In the 1940s, government leaders called upon the prestigious philosopher to write political tracts in support of Japanese expansionism. These writings were too abstract for politicians and military leaders, but were attacked as pro-Western by right-wing philosophers of the day, and later as imperialist by leftist critics. Because of his interest in Zen, his adaptation of Mahāyāna Buddhist logic and his influence on younger Kyoto colleagues such as Tanabe Hajime and students such as Nishitani Keiji, Nishida became known as the father of the 'Kyoto School' that dominated Japanese philosophy of religion up to the 1990s and informed much Buddhist-Christian dialogue (see Kyoto School). It is possible, however, to understand 'Nishida philosophy' in a different light, as a systematic deconstruction of logical relations.

Four methods are evident in the development of Nishida's philosophy and help to clarify it. First is his way of laying a foundation; then, undermining or undergirding that foundation with something more basic, and ultimately, undermining any positive determination of a foundation. This method has similarities with that of Nāgārjuna, except that Nishida works on broad foundations in several major treatises instead of particular propositions in a single analysis. Second, there is his way of subverting anthropocentric assumptions about the nature of knowledge and reality. Third, there is his method of exhibiting the self-reflective or self-mirroring structure of many logical and metaphysical categories. Fourth, there is his reversal of the order of things in many traditional hierarchies or explanatory schemes.

The preface to *Zen no kenkyū* expresses Nishida's initial project to explain everything on the basis of pure experience as the single reality. Pure or immediate experience is the moment or act of experiencing before there is an awareness of any difference between an object that is experienced and a subject who does the experiencing, before there is any thought, reflection or meaning. This singular and unitary foundation develops to include derivative and differentiated moments such as thought and reflection that seek a higher unity in reality. Reality objectified and unified as a whole is what is meant by nature, but as the activity of unifying it is spirit. Nishida undermines subjectivist views of experience by claiming that it precedes and founds the individual human subject; he subverts appeals to an ultimate difference between reality and consciousness, and he distances himself from anthropocentric views of consciousness by using the word 'God' for the infinite activity of unification. Unlike many commentators who see the notion of pure experience as the basis of all of Nishida's philosophy, however, he himself soon abandoned this notion, perhaps because of its psychological connotations, or perhaps because of its inherent logical difficulty in accounting for a meaningful world that arises from a meaning-less foundation.

Jikaku ni okeru chokkan to hansei (Intuition and Reflection in Self-Consciousness), written serially from 1913 to 1917, at first continues the project to explain immediate experience as a dynamic system that develops into reflective thought and judgment. Nishida follows neo-Kantians in undercutting the traditional fact-value distinction; factual judgments intend truth that serves as a value or norm (see Neo-Kantianism). He appeals to the notion of intellectual intuition as a way to reconcile immediate experience with reflection, which coincide in the case of intuited self-awareness. By the end of this work he has shifted the foundation to what he considers the primary instance of self-awareness, namely absolute free will, because its activities of creating and valuing are

more basic than intellectual knowing (see Free will). In *Ishiki no mondai (Problems of Consciousness)*, Nishida reverses the usual primacy not only of knowing over valuing, but also of feeling over willing and sensing over feeling, by proposing that the latter term of each pair is the more concrete reality. *Geijutsu to dōtoku (Art and Morality)* names the absolute will as the source of moral decision making and creative artistic activity. In later works, however, Nishida eventually abandons the notion of absolute will as a basis, because the activity of the will eludes reflection and thus would be an unknowable foundation.

Essays in *Hataraku mono kara miru mono e (From That Which Acts to That Which Sees)* and *Ippansha no jikakuteki taikei (The Self-Conscious System of Universals)* begin to develop Nishida's 'logic of place' (*basho*). His notion of a universal (see Universals) as a place may be interpreted as a founding level of discourse that resolves contradictions on less comprehensive levels. Ultimately, the place that holds differences or contradictions together is absolute nothingness, the place beyond discursive determination. This notion undermines previous attempts to locate a foundation with a positive description such as pure experience, self-awareness, or absolute will. Yet the self-reflective structure of self-awareness, in which a whole is mirrored or reflected in a part of itself, is still evident in universals of all levels, including the ultimate nothingness. We may read 'self-reflective' for the term 'self-conscious' (*jikakuteki*) in the above works, or in *Mu no jikakuteki gentei (The Self-Conscious Determination of Nothingness)*, published in 1932.

In *Tetsugaku no kompon mondai (The Fundamental Problems of Philosophy)* and seven volumes of *Tetsugaku ronbunshū (Philosophical Essays)*, Nishida shifts from the scheme of place within place (in other words, less and more inclusive contexts) to the notions of 'absolutely contradictory self-identity' and 'the world as a dialectical universal'. The former notion lets opposites form unities through continual self-negation, for example, that of the world or the self, each a contradictory unity of many and one, and a 'continuity of absolute discontinuities'. The notion of the dialectical universal implies that the world is not another entity but rather a place of mediation between individuals that co-arises and is codetermined with them. The exemplary case of individuality is not a material (and abstract) object like an atom, but rather the concrete human self, the focal point where the world reflects itself in itself. The self is not a subject that can be defined by adding specific differences to a genus (see Aristotle §§7-8), but rather something that forms itself through continual self-negation of its previous identities, in other words, through 'acting intuition', acting arising from direct seeing. Self and world both find their immediate 'ground' in absolute nothingness, for nothing outside them can serve as their basis and yet they do not serve as a foundation for themselves.

Partially in tension with this individualism is the theme that the world in its most concrete manifestation is a historical world determined by the interaction of different selves. Nishida's turn towards a philosophy of history from 1931 onwards culminated in a political and cultural philosophy, pronounced in the early 1940s, that envisaged a new, truly global world of nation-states (see Nation and nationalism). Each has its own principle that forms it in difference from and in interaction with all others. The state is the source of moral values. Nishida's own warning that Japan should not become imperialist is belied in his view that Japan is the nation-state that can awaken other nations, particularly Asian ones, to their truly global identities. The historical position of the Emperor is the empty centre of the body of the nation (*kokutai*) and the place from which emerge the creative possibilities of Japan as a nation and of being Japanese. In contrast to a view of history that sees present circumstances determined by past events and decisions oriented toward the future, Nishida sees history forming out of the 'absolute present' in which past and future are simultaneously co-present, each negating the other to allow infinite possibilities.

Nishida's last writings continue this nationalism but also make more explicit the religious themes latent throughout. In particular, *Bashoteki ronri to shūkyōteki sekaikan (The Logic of Place and the Religious Worldview)*, published in 1945, addresses personal concerns of religious awareness and the death of the individual self. There the basic Other to oneself is not another self, nor the world as dialectical universal, nor even absolute nothingness, but rather the absolute or God (see Absolute, the; God, concepts of). The relation between the individual self and God is a kind of contradictory self-identity, more properly called an 'inverse correspondence' (*gyakutaiō*). The self properly relates to God only by dying to itself, to ego (a death that is not the same thing as the nihilation of the person), and so becomes its true self. For its part, the absolute arises through its self-negation in the relative self; it does not exclude the relative, nor even evil. Although God 'is absolute being only because he is absolute nothingness', this essay's implicit accommodations to Christian theism and Pure Land

Buddhist faith seem at odds with Nishida's earlier anti-foundation of absolute nothingness.

Nishitani Keiji (1900-90)

Nishitani Keiji is generally regarded as the leading light of the 'second generation' Kyoto School of modern Japanese philosophy. Influenced by Zen thinkers from Chinese and Japanese Buddhism as well as by figures from the Western mystical and existential traditions, he is a pre-eminent voice in East-West comparative philosophy and late twentieth-century Buddhist-Christian dialogue. Primarily a philosopher of religion, Nishitani strove throughout his career to formulate existential responses to the problem of nihilism.

A student of the foremost figure in modern Japanese philosophy, Nishida Kitarō, Nishitani Keiji spent most of his life writing and teaching in Kyoto and became one of the most prominent members of the Kyoto School of philosophy (see Kyoto School). His earliest thinking developed under two different sets of influences. A classical education acquainted him with the Chinese Confucian and Buddhist traditions as well as with the philosophies of the Japanese schools of Zen Buddhism (see Buddhist philosophy, Japanese), where he found the thinking of Dōgen, Hakuin and Takuan most congenial. At the same time he read widely among Western authors (he mentions in particular Nietzsche and Dostoevskii, Emerson and Carlyle, as well as the Bible and St. Francis), and soon began to tackle such thinkers as Plotinus, Meister Eckhart, Schelling and Heidegger. By his own account, his engagement with philosophy was not the result of an intellectual decision but was precipitated by a severe existential crisis in his youth.

In 1936, Nishitani went to study philosophy in Germany and ended up in Freiburg, where he worked closely with Heidegger, returning to Japan on the eve of the Second World War. The next several years saw the publication of a number of texts on political themes (some of which were clearly written under external pressure). Although some internationalist elements in these writings provoked the ire of the right wing at the time, Nishitani was subsequently relieved of his teaching duties at Kyoto University for several years on the grounds of the inflammatory 'nationalist' tone of his wartime writings. While he has been reviled by Marxists in Japan and the USA for his 'rightwing' politics, Nishitani's published works of the period are mild compared to those of some other members of the Kyoto School; and among the critics, political innuendo has generally substituted for contextualized readings of the relevant texts.

Nishitani's long-standing engagement with the problem of nihilism was furthered in a series of talks subsequently published in 1949, the Japanese title of which was simply *Nihirizumu (Nihilism)*. In the framework of a synoptic account of nihilism as a historical phenomenon arising in nineteenth-century Europe, the author goes on to take it as an immediately existential problem. With the main focus on Nietzsche and a secondary concern with such thinkers as Max Stirner and Heidegger, he shows their common concern with the issue of what he calls 'the fundamental integration of creative nihilism and finitude'. By this is meant that when the self is plumbed to sufficient depth, and if one can endure the experience of the *nihilum*, or void, at its base, that 'nihility' may eventually be realized as a creative nothingness. Turning at the end of the book to nihilism in modern Japan, Nishitani argues that the Nietzschean project of 'the self-overcoming of nihilism' has close parallels to 'the standpoint of Buddhism, and in particular to the standpoint of emptiness in the Mahāyāna tradition' (see Buddhist concept of Emptiness; Buddhist philosophy, Japanese). On this view, the nothingness of the abyss in Nietzsche would be similar to the nothingness (*mu*) or fertile emptiness (*kū*) that is central to Japanese Buddhist thinking.

The text that is widely regarded as Nishitani's most important work, *Shūkyōto wa nani ka? (What Is Religion?)*, came out of a series of essays written in the late 1950s and was first published in book form in 1961. The emphasis is now very much on the Zen Buddhist tradition, with a secondary focus on Christianity and certain figures in Western philosophy (Meister Eckhart, Nietzsche, Heidegger). Like his teacher Nishida and several other senior members of the Kyoto School, Nishitani sees the Zen notion of 'absolute nothingness' as central to both philosophy and religion. True to the Mahāyāna Buddhist tradition, he stresses that absolute nothingness cannot be properly grasped by intellect alone but must rather be thought and experienced as the field or place from which all our thoughts and actions can flow. He thereby elaborates a radically non-anthropocentric worldview that allows us to realize ourselves as fully human beings-in-the-world, and from which the nothingness discussed by Nietzsche and Heidegger can be seen to 'fall short' of the Mahāyāna notion. However, to avoid entering a debate in competitive (rather than comparative) philosophy, let it simply be said in conclusion that the 'double genealogy' of

Nishitani's thinking - incorporating strains of Confucian, Daoist and Buddhist thinking on the one hand, and Neoplatonic, Christian mystical, and German idealist and existential philosophy on the other - gives rise to a uniquely formidable philosophy.

Nominalism

'Nominalism' refers to a reductionist approach to problems about the existence and nature of abstract entities; it thus stands opposed to Platonism and realism. Whereas the Platonist defends an ontological framework in which things like properties, kinds, relations, propositions, sets and states of affairs are taken to be primitive and irreducible, the nominalist denies the existence of abstract entities and typically seeks to show that discourse about abstract entities is analysable in terms of discourse about familiar concrete particulars.

In different periods, different issues have provided the focus for the debate between nominalists and Platonists. In the Middle Ages, the problem of universals was pivotal. Nominalists like Abelard and Ockham insisted that everything that exists is a particular. They argued that talk of universals is talk about certain linguistic expressions - those with generality of application - and they attempted to provide an account of the semantics of general terms rich enough to accommodate the view that universals are to be identified with them.

The classical empiricists followed medieval nominalists in being particularists, and they sought to identify the kinds of mental representations associated with general terms. Locke argued that these representations have a special content. He called them abstract ideas and claimed that they are formed by removing from ideas of particulars those features peculiar to the particulars in question. Berkeley and Hume, however, attacked Locke's doctrine of abstraction and insisted that the ideas corresponding to general terms are ideas whose content is fully determinate and particular, but which the mind uses as proxies for other particular ideas of the same sort.

A wider range of issues has dominated recent ontological discussion, and concern over the existence and status of things like sets, propositions, events and states of affairs has come to be every bit as significant as concern over universals. Furthermore, the nature of the debate has changed. While there are philosophers who endorse a nominalist approach to all abstract entities, a more typical brand of nominalism is that which recognizes the existence of sets and attempts to reduce talk about other kinds of abstract entities to talk about set-theoretical structures whose ultimate constituents are concrete particulars.

1 Introduction

In one use, 'nominalism' refers to a cluster of loosely-related philosophical and theological themes articulated by certain late fourteenth-century thinkers who were influenced by William of Ockham. These thinkers expressed doubts about the Aristotelian metaphysics, in particular its use in proving God's existence. They gave priority to faith over reason and emphasized the omnipotence of God in ways that often led to a Divine Command theory in ethics and a general scepticism about our knowledge of both causal relations and the substance-accident distinction.

Used this way, the term has its roots in the more common use which refers to a general theoretical orientation to questions about the existence and nature of abstract entities, an orientation exemplified in the work of Ockham himself. Those who are nominalists in this sense reject a Platonistic or realistic interpretation of discourse about things as diverse as properties, kinds, relations, propositions, sets, states of affairs and modality. Sometimes the nominalist is said to endorse the view that discourse of the sort in question is metalinguistic and that talk about the so-called abstract entities is really just talk about *nomina* or linguistic expressions. Characterized in this way, nominalism is sometimes said to stand opposed to conceptualism, another reductionist approach to ontological questions about abstract entities. The claim is that while the conceptualist insists that it is necessary to make reference to the activity of conceptual representation to accommodate the recalcitrant discourse, the nominalist denies this. But, first, not all of those who are called nominalists endorse a metalinguistic interpretation of the disputed discourse; and, second, since few philosophers have thought it possible to characterize language without referring to conceptual activity, to take nominalism as a view opposed to conceptualism yields the result that few of those thinkers normally taken to be nominalists turn out to deserve that label. Accordingly, it has become customary to construe as nominalistic any reductive approach to ontological questions about abstract entities that stands opposed to the Platonistic view.

2 The medieval period

The orientation we call nominalism is typically traced back to medieval debates over universals. A major source of

these debates was Boethius' commentary on Porphyry's *Isagoge*, where we find a detailed discussion of the ontological status of universals (see Boethius, A.M.S.; Porphyry §1). Boethius' commentary became a pivotal text for medieval philosophers, and by the twelfth century the debate over universals had become a dominant topic of philosophical concern. Two opposing views emerged. One, championed by William of Champeaux, was an extreme form of realism. On this view, a genus or a species is literally the same in all its members; the individuals falling under the kind are rendered distinct by the addition of forms to the common essence, and those forms are predicates of the essence. The opposing view, defended by Roscelin of Compiègne, represented an extreme version of nominalism. Insisting that all entities are particulars, Roscelin argued that talk of universals is merely talk about linguistic expressions that can be applied to a number of different particulars, and he held to an austere interpretation of linguistic expressions where universals are mere *flatus vocis* or vocalizations.

Abelard attacked both views (see Abelard, P. §5). He argued that since the forms which allegedly diversify any common essence are contraries, William's realism commits us to the view that a single entity can simultaneously exhibit incompatible properties; and he appealed to Aristotle's definition of the universal as that which can be predicated of many to call into question the claim that nonlinguistic entities can be universals. That definition, he contended, applies exclusively to things that can function as predicates in subject-predicate sentences, to what we nowadays call general terms. But while agreeing with Roscelin that we can 'ascribe universality to words alone' Abelard rejected Rocelin's claim that universals are mere *flatus vocis*, insisting that they are expressions that are significative or meaningful; and he argued that any adequate account of universals must show how, in the absence of a common essence, general terms can be meaningful. In doing so, it must answer two questions: (1) what is the cause of the imposition of a common name; and (2) what is it that we grasp when we grasp the signification of a common name?

Abelard's answer to the first question is disarming. The things to which the term 'man' applies, for example, all agree in being men. Their being men is the ground of the imposition of the common name 'man'. Abelard denies, however, that this agreement involves any common entity. He takes it to be an irreducibly primitive fact that all the things called men agree in that they are all men. In response to the second question, Abelard argues that what we grasp when we understand the common name 'man' is not any of the particular men named by that term; nor is it the collection consisting of all those particulars. To explain the kind of cognition associated with general terms, Abelard appeals to the distinction between perception and intellection. In perception, we grasp the particular named by a proper name; the cognition associated with general terms is, however, intellective. Here, the mind is directed toward an object of its own making, a *res ficta*. The *res ficta* is a kind of image, one that is *communis et confusa* (common and indifferent). It is common to all the items named by the associated general term and proper to none. Accordingly, it represents them all indifferently. Since it is something distinct from any of the particulars that fall under the Aristotelian categories, it is neither a substance nor an accident. It is the product of the intellect's activity of abstraction, and it is what is signified by the associated general term - it is what we grasp when we understand such a term.

The century after Abelard brought a number of different developments. The appearance of the complete Aristotelian corpus gave a clearer picture of Aristotle's views on universals, and the rich framework of semantical concepts associated with the developing terminist logic made possible the articulation of a more powerful form of nominalism than those defended by Roscelin and Abelard. That articulation came from William of Ockham (see William of Ockham §6). Following terminist logicians, Ockham distinguished between categorematic and syncategorematic terms. Categorematic terms are expressions whose significance derives from their having a 'definite and determinate signification'. Syncategorematic terms, by contrast, do not serve as signs of objects; their significance derives from the roles they play when used in conjunction with categorematic terms. Categorematic terms are further divided into discrete and common terms, where this is the contrast between expressions that signify just one object and expressions that signify many and so are predicable of many.

Like Abelard, Ockham identifies universals with common terms. Insisting that every existing thing is a particular, he construes the distinction between universals and particulars as a distinction between categorematic terms that signify just one thing and those that signify many. But where Abelard takes conceptual representations to be nonlinguistic items that function as the significata of the various common terms, Ockham wants to claim that a common term like 'man' signifies the various particulars of which it is truly predicable, and that the conceptual representation corresponding to the term 'man' is itself a linguistic entity. His idea is that thinking is inner

dialogue, best understood by way of the familiar concepts appropriate to spoken and written language. Thus, concepts are mental terms, judgments are mental propositions, and inferences are mental syllogisms. Conceptual linguistic items differ, however, from spoken or written words in that while the latter are only conventionally significant, the former are natural signs. The phoneme ‘man’ has the meaning it does only by virtue of a complicated system of conventions, but the concept *man* is something whose intrinsic nature it is to play the linguistic role it does; and although we describe conceptual representations by the use of concepts derived from our characterization of spoken and written language, mental language is prior to both. Just as written language is an outgrowth of spoken language, spoken language is an extension of mental language, a sort of ‘thinking out loud’.

The distinction between discrete and common terms, therefore, applies to conceptual representations, so that there are conceptual universals - conceptual representations that are predicable of many - and these are the genuine universals. Since they are naturally significant, the common terms of mental language are in their intrinsic nature items predicated of many; and their universality is the root of the merely conventional universality of the common terms of spoken and written language. Corresponding to the spoken/written term ‘universal’ there is a mental common term *universal*. To bring out the contrast between his own form of nominalism and its realist alternatives, Ockham tells us that this mental term is a term of second rather than first intention; it is a term that signifies not extramental entities but, rather, intentions of the soul, those that are in their intrinsic nature signs of many.

In characterizing the conceptual items that are in their intrinsic nature universals, Ockham mentions three possible views. One harkens back to Abelard and construes the mental term as a *res ficta* not found in any Aristotelian category; a second construes mental terms as qualities of the soul that serve as objects of its acts of understanding; the third identifies the mental term with the act of understanding itself. Over the course of his career, Ockham wavers between these views, but he ultimately comes to endorse the third view on grounds of theoretical simplicity.

Ockham’s nominalism extends beyond a concern with universals and the distinction between common and discrete terms. He is also interested in the distinction between concrete and abstract terms, between terms like ‘man’ and ‘humanity’, ‘courageous’ and ‘courage’, and he is concerned to undermine what initially appears to be a plausible account of this distinction. A natural response to the distinction is to say that whereas concrete terms signify familiar concrete particulars (the particulars which are men and courageous), their abstract counterparts signify the abstract entities (humanity and courage) those particulars exhibit. Since the distinction between concrete and abstract terms is found in all ten Aristotelian categories, the view unfolds into the claim that for each category there is a categorically different kind of abstract entity such that, in virtue of exhibiting an entity of that kind, a particular comes to be characterized by the appropriate concrete term.

In combating this view, Ockham argues that the categories do not represent a classification of nonlinguistic objects; they are, rather, a classification of linguistic expressions according to their mode of signification. As he sees it, there are nonlinguistic objects corresponding only to the categories of substance and quality, and the entities in question are all particulars. So there are particular substances (like this man) and particular qualities (like the whiteness of this piece of paper). Abstract terms from the category of substance do not signify anything distinct from the particular substances signified by their concrete counterparts. Abstract terms from the category of quality do tend to signify entities distinct from the familiar substances that we say are white and courageous; but a term like ‘courage’ does not signify some one quality that all courageous individuals share. ‘Courage’ is better construed as a general term signifying individual qualities, the various courages in virtue of which individual human beings are called courageous. In none of the other Aristotelian categories do abstract terms signify any entities distinct from those signified by their concrete counterparts. Indeed, Ockham wanted to claim that abstract terms from categories other than that of quality are eliminable from discourse, that sentences incorporating terms like ‘paternity’ and ‘burglary’ can be replaced, without loss of content, by sentences in which those terms do not appear, but their concrete counterparts (‘father’ and ‘burglar’) do; and a significant portion of his ontological/logical works is dedicated to showing how these translations are to go (see Aristotelianism, medieval).

3 Classical British empiricism

The classical empiricists followed Abelard and Ockham in denying that general terms signify universals. Thus, Hobbes sounds a familiar theme when he tells us that the only things that exist are particulars and that the terms

'general' and 'universal' are just 'names of names'. Like their medieval forbears, the empiricists recognized that the plausibility of this view hinges on our ability to provide a satisfactory account of the relation between general terms and the inner representations or ideas corresponding to them. Locke, who agrees that extramental entities are one and all particulars, argues that words signify ideas and that the ideas corresponding to general terms are abstract ideas - ideas formed from our ideas of particulars by separating out the features peculiar to this or that particular, retaining 'only what is common' to all the things to which a given general term applies. Berkeley goes further in his nominalism, denying that we have abstract ideas of the sort Locke describes. On Locke's view, the process of forming an abstract idea of a triangle, for example, consists in separating out all those features with respect to which triangles differ; and the result of this process is an idea of a triangle that is 'neither oblique nor rectangle, neither equilateral nor equicrural nor scalenon, but all and none of these at once'. Berkeley challenges us to identify an idea that corresponds to this characterization. As he sees it, our ideas are determinate in all their features and, accordingly, particular in their content (see Hobbes, T. §3; Locke, J. §6; Berkeley, G. §2).

While Berkeley attacks the view that ideas are general in virtue of being abstract, he concedes that there are general ideas; but he insists that the generality of an idea is a function of its role in thinking rather than any special kind of content. Ideas are general not because they result from abstraction in Locke's sense, but because the idea is made 'to represent or stand for all other particular ideas of the same sort'. So the mind takes an idea that is fully determinate and particular in its content and makes it stand for other ideas of the same kind. Hume wholeheartedly endorses Berkeley's attack on abstraction and his account of generality, telling us that general ideas are ' in themselves individual, however they may become general in their representation. The image in the mind is only that of a particular object, though the application of it in our reasoning be the same as if it were universal' (Hume [1740] 1978: 20).

4 The twentieth century

Like ontological debates in earlier periods, ontological discussions in early analytic philosophy typically focused on the problem of universals. Thus, Frege, Moore and Russell were all anxious to undermine nominalistic theories that seek to analyse subject-predicate discourse without reference to nonlinguistic universals; and when the later Wittgenstein attacks the view that the use of a general term like 'game' is grounded in the antecedent recognition of a property or set of properties common to all the items to which the term applies, he is, among other things, challenging their Platonistic accounts of subject-predicate discourse (see Wittgenstein, L. §9). Although concern with universals has continued throughout the twentieth century, the investigations of recent nominalists bear on a wider range of issues than those of their medieval and classical modern forbears. In addition to concern with universals, contemporary nominalists attempt to provide reductive accounts of things as diverse as the mathematician's sets, propositions, states of affairs, events and possible worlds, and philosophers of a nominalistic spirit take different attitudes towards different items on this list. Some, for example, are nominalists with regard to the traditional universals while insisting on a Platonistic account of sets; others insist on the irreducibility of events while providing reductive accounts of discourse apparently about propositions, states of affairs and universals. Indeed, few philosophers have been willing to defend a nominalistic approach to all of the so-called abstract entities. One exception is Wilfred Sellars (see Sellars, W. §2).

The account given by Sellars is an elaboration of Ockham's suggestion that talk about abstract entities is metalinguistic discourse. This suggestion had previously been elaborated in a proposal by Rudolf Carnap *The Logical Syntax of Language* that we construe talk about abstract entities as pseudo-material mode discourse, discourse apparently, but not really about nonlinguistic objects (see Carnap, R. §3). Carnap's concern is with sentences of the following sort:

(1) Courage is a property.
(2) Mankind is a kind.
(3) Paternity is a relation.
(4) That two plus two equals four is a proposition

His proposal is that we treat these sentences as disguised ways of making claims about the syntax of certain linguistic expressions. Thus, (1)-(4) become:

(1′) 'Courage' is an adjective.

(2′) ‘Man’ is a common noun.
(3′) ‘Father of’ is a many-place predicate.
(4′) ‘Two plus two equals four’ is a declarative sentence

The difficulty with this proposal is that (1)-(4) turn out to be claims about *English* expressions. The proposal forces us to take the Spanish counterparts of (1)-(4), for example, to be claims about *Spanish* words, so that (1)-(4) and what are supposed to be their Spanish translations do not even agree in reference. Sellars responds to this problem by introducing a kind of quotation that cuts across languages, called dot quotation. Whereas standard quotation of the sort we meet in (1′)-(4′) creates metalinguistic expressions that apply exclusively to words in the quoting language, the application of Sellars’ dot quotation to an expression creates a metalinguistic common noun that is true of all those expressions, regardless of language, which play the same linguistic role that the quoted expression plays in the base language. Thus, ‘ ·man·’ is a common noun true of ‘hombre’, ‘homme’, and ‘Mensch’. In their respective languages, these terms play the same role that ‘man’ plays in English; they are all ‘ ·man·’s. Now, Sellars wants to claim that using the machinery of dot quotation, we can provide a satisfactory reconstruction of (1)-(4) as:

(1″) ·Red·s are adjectives.
(2″) ·Man·s are common nouns.
(3″) ·Father of·s are many-place predicates.
(4″) ·Two plus two equals four·s are declarative sentences.

As Sellars understands them, (1″)-(4″) represent claims about linguistic expressions construed as tokens rather than types; and talk of linguistic tokens can be recast as talk about speakers and inscribers. Even the apparent Platonism involved in talk about linguistic roles is illusory since talk about linguistic roles can be eliminated by reference to talk about the linguistic rules that govern the use of terms. Accordingly, talk apparently about abstract entities is consistent with the most austere nominalism; it is merely metalinguistic discourse that cuts across languages.

Sellars believes that the sort of account he proposes for (1)-(4) can be extended to handle all discourse involving the so-called abstract entities. A slightly less radical form of nominalism is found in the writings of W.V. Quine (see Quine, W.V. §6). Early in his career, Quine espoused a nominalism as austere as that developed by Sellars, but by the time he wrote *Word & Object* (1960), he had concluded that there is one kind of abstract entity whose existence we have to acknowledge, the mathematician’s set or class. Quine remains unwilling to recognize things like properties, relations, kinds, and propositions, however. Unlike sets, these alleged entities lack clear-cut identity conditions and should play no role in our ontology.

Most contemporary philosophers agree with Quine that we must endorse an ontology of sets. This view provides the backdrop for the reductive approach to universals defended by G.F. Stout and D.C. Williams. They hold that there are particular as opposed to general qualities or properties, things like the whiteness of this piece of paper. So there are abstract entities besides sets; but they are one and all particulars. Williams calls these abstract particulars *tropes* and he tells us that they constitute ‘the alphabet of being’. Tropes are ontologically primitive, and items from other categories are constructions out of them. Thus, the universal of the Platonist is a set of resembling tropes; and familiar concrete objects are bundles of tropes that contingently enter into a relation of ‘collocation’.

Although Williams’ trope-theoretic nominalism continues to enjoy some popularity, the most prominent form of nominalism in the contemporary arena is that influenced by developments in the semantics of modal logic, where we meet the idea that the actual world is just one of infinitely many possible worlds and that the totality of possible worlds constitutes the subject matter for talk about necessity and possibility (see Possible worlds). Contemporary nominalists claim that the framework of possible worlds provides the resources for a genuinely reductive account of things like properties and propositions. These philosophers propose that we take possible worlds as primitive. Each such world, they claim, can be characterized in nominalist terms as a totality of concrete particulars, and they argue that we can provide a nominalist treatment of things like properties and propositions by identifying them with set-theoretical entities of a transworld sort. We can identify properties with functions from worlds to sets of objects, relations with functions from worlds to sets of ordered n-tuples and propositions with sets of worlds or functions from worlds to the truth values. The most prominent proponent of this sort of view is David Lewis (see

Lewis, D. §3). He has invoked the framework of possible worlds not simply to provide an account of properties and propositions, but to clarify the concept of meaning, to state truth conditions for counterfactuals, and to provide an analysis of causation (1986).

Nominalism, Buddhist doctrine of

Buddhist nominalism refers to the nominalist ontology and semantics developed especially by the Indian Buddhist philosophers Dignāga and Dharmakīrti. Elaborating on the arguments of their Buddhist predecessor Vasubandhu, they critically examine the notions of spatial and temporal extension. For Dignāga and Dharmakīrti, spatially and temporally composite entities are constructed through concepts and language and as such those entities exist only nominally or conventionally. Their semantics rejects the realist position that expressions refer to real, extra-mental universals that are instantiated in each particular of the class formed by the respective universal. Instead, these philosophers developed the unique theory of 'exclusion' whereby expressions convey meaning by the exclusion of some particulars from those which do not have the expected causal capacities. Dharmakīrti's nominalism is credited with a greater impact on Indian philosophy than Dignāga's.

1 Ontology

One can reduce the concerns of Buddhist philosophers to a central preoccupation: the cessation of suffering. According to Buddhist philosophers, the elimination of suffering (*duḥkha*) requires the elimination of its cause, which is thought to be the belief in entities that in fact do not exist (see Suffering, Buddhist views of origination of). Of particular concern is the belief in an eternal, unchanging self or soul (*ātman*), for this belief motivates the behaviour that produces suffering. Buddhists before Dharmakīrti often employed part or whole arguments to refute the notion of self and eventually to reject all composite entities. These arguments, which inform much of Dharmakīrti's nominalism, can be summarized by briefly examining a composite entity, such as a table.

Although a table is apparently a single entity composed of various parts, Buddhists question whether any such entity actually exists. They ask whether the whole that is the table is the same as or different from its parts. If the whole differs from its parts, what evidence do we have for its existence? Immediate sensory perception yields information only about the parts. If the whole is the same as its parts, then it must be either fully or partially instantiated in each part. If it is fully instantiated in each part, then any single part is an entire table. If the table is only partially instantiated in its parts, then we should speak of many partial tables rather than one single table. If we were to claim that all the parts together are the table, then a heap of table-parts should be a table. Finally if the parts in a particular configuration are the table, one could again ask whether that configuration is the same as or different from the configured parts: an infinite regress ensues.

Expanding on this critique of spatial extension, Dharmakīrti also attacks temporal extension. In doing so, he affirms the doctrine of momentariness, whereby an ultimately real entity can only exist for an infinitesimal period of time (see Momentariness, Buddhist doctrine of). This doctrine is supported in part by the argument that an entity which does not change over time cannot produce any effects, for a cause must change from a pre-production state to a post-production state; otherwise, it would either produce its effects at all times eternally, or it would never produce any effect. Furthermore, Dharmakīrti maintained a causal model of sense perception whereby a sensed entity causes the content of one's sensory cognition. Since a nonmomentary entity could never act as a cause, it could never be perceived. As a result, one could never indubitably establish its existence, for in Dharmakīrti's words, 'to exist is to be perceived' (*sattvam upalabdhir eva*) (*Pramāṇavārttikasvopajñavṛtti on Pramāṇavārttika* I.3ab).

In short, Dharmakīrti denies that any composite entity can be real in the strictest sense. However, following his predecessors, he admits that composite entities can be said to exist from the perspective of conceptual and linguistic conventions. These modes of existence yield two important categories: things that exist in the strictest sense are 'ultimately' real (*paramārthasat*), while those contingent upon linguistic and conceptual conventions are only 'nominally' (*prajñaptisat*) or 'conventionally' real (*saṃvṛtisat*).

2 Critique of universals

Dharmakīrti's most thorough analysis of semantic issues appears in the *Svopajñavṛtti (Interpretative Commentary)*, his lengthy remarks on the first chapter of his *Pramāṇavārttika (Comments on Instrumental Knowledge)*. Much of his work concerns the problem of repeatability or universality (*anvaya*). In other words, when I use the expression 'cow', for example, what is it about all cows that allows me to apply this one word to all

of them? On the pre-reflective intuitions suggested by language, it seems that there is something the same about all cows. Elaborating on this intuition, most Indian philosophers maintained that there is in fact some real entity - in this case, 'cowness' - that is instantiated in each cow. Entities such as 'cowness' are called 'universals' (*sāmānya, jāti*) and they are instantiated in 'particulars' (*vyakti, svalakṣaṇa*), the things that impinge on our senses and which we seem to identify as 'cows'. Here, the technical term 'referent' might be used in a way that differs from some of its more common uses in Western philosophy. That is, to describe the view of Indian realism, the actual referent of the expression 'cow' might best be considered the universal 'cowness' itself (see Universals, Indian theories of).

When Dharmakīrti attacks this view, he maintains that an expression is successful in its semantic function only when it has induced an action (*pravṛtti*) towards the intended particular in the person who has apprehended that expression. Such action might be some physical manipulation of the particular or a mere cognitive act such as recognition. That being the case, ultimately real universals make meaning impossible because expressions which refer to ultimately real universals would be incapable of inducing action towards particulars.

To demonstrate this conclusion, Dharmakīrti raises the problem of identity and difference as a species of the part or whole analyses previously mentioned. He asks whether the universal is the same as or different from the particulars in which it is instantiated. If the universal is different, then the expression 'cow' would not induce acts towards any particular because it refers only to the universal 'cowness', which is entirely distinct from any particular. One might still insist that the expression can induce action towards the intended particular, but then one must admit that an expression can induce action towards any entity, whether it be the same as or different from its referent.

On the other hand, if the universal is identical with the particulars, then the universal would lose its universality or repeatability. In other words, a cow-particular must be distinct from all other cow-particulars, otherwise, one would be unable to distinguish one cow from any other. Hence, a cow-particular is not repeatable - one cow-particular does not occur in or as any other cow-particular. But if the universal 'cowness' is identical with any cow-particular, then it would also be unrepeatable. One would need a new universal for every instance and the expression 'cow' could only be applied to that one particular, which is identical to the universal 'cowness'.

In response, some Indian realists admit that the particular and universal must be distinct, but they claim that an expression which refers to a universal can induce action towards a particular by virtue of the particular's relation to the universal. Among the more compelling criticisms of this position is Dharmakīrti's contention that any form of relation necessarily leads to either a contradiction or an infinite regress. That is, a relation's relata must be either the same or different. If they are the same, then there is no relation, for relations presuppose difference. If, on the other hand, the relata are different, then they cannot be in relation, for if entirely distinct entities can stand in relation, then one can haphazardly relate any entity to any other entity. The notion of relation would thus be meaningless. Only a contradiction remains: the relata are both the same and different. If in response one posits a subsistent relation that 'ties' the relata together, one must then explain how the relata are related to the relation. If one then speaks of some second-order relation that connects the relata to the relation, one falls into an infinite regress.

3 Theory of meaning

Dharmakīrti's ontology can be reduced to the claim that the ultimately real is necessarily unique and unrepeatable. Hence, he rejects realist semantics because a universal must be in some sense repeatable in each of its instances. Yet without real universals, how do we explain our ability to use language? The Buddhist answer is that expressions convey meaning by the exclusion of some particulars from those which do not have the expected causal capacities. In this respect, meaning has three components: the cognitive image (*pratibhāsa, ākāra*), the particular and the exclusion (*vyāṛtti*).

For Dharmakīrti, language operates in the same fashion as conceptual thought. We can most easily examine the role of cognitive images by turning to the cognition called 'recognition' (*pratyabhijñāna*) - the conceptual act whereby a sensed object is identified or labelled. For recognition to occur, one must have learned the conventions that govern the appropriate expression or concept. If, for example, one knows the conventions that govern 'cow', one can have the recognition, 'that is a cow'. For Indian philosophers the important question is, what is it that we label with concepts or expressions such as 'cow'?

In discussing recognition, Dharmakīrti assumes a causal model of sense perception: when some particular impinges upon the senses, that particular creates an image in the mind. This image or sensum is what one knows in sense perception. This means that what we recognize as a 'cow' is not some particular that impinged upon the senses; rather, it is the image produced in our minds by that particular. Hence, if expressions and concepts give us any knowledge of particulars, they do so only by the mediation of the cognitive images caused by those particulars.

Objectors to this position point out that if concepts and language yield knowledge just of cognitive images, then actions based on such knowledge would be focused upon images and not upon particulars. Dharmakīrti responds that ordinary persons have a deeply inculcated cognitive habit of mistaking the images that arise from particulars for those particulars themselves. This claim leads to his assertion that all linguistic and conceptual knowledge is flawed in that it rests upon the conflation of the image with the particular that caused it. Dharmakīrti remarks that this psychological apparatus explains how images can induce action towards particulars. He further notes that an image nevertheless can yield useful information because it directs one only towards the particular which acted as its cause.

In appealing to the causal link between images and particulars, Dharmakīrti makes a crucial statement about images. That is, Dharmakīrti argues that any entity which acts as a cause or effect is a particular and since images are effects, they must be mental particulars. As particulars, images are never repeatable, so images cannot be the same in all cases when we use a given concept or expression. Instead, Dharmakīrti maintains that what is actually the same in all cases are 'exclusions'.

His theory begins with the claim in the *Pramāṇavārttikasvopajñavṛtti on Pramāṇavārttika* (I, V 107-9; 119-43) that all images of tables, for example, produce an effect that no non-table produces: a second-order cognition called the 'determination of sameness' (*ekapratyavamarśajñāna*) in which any table-image is determined to be the same as every other table-image in that they are all imagined to be tables. Hence, all table-images are the same in that they all produce a cognition of their sameness. Since those images were produced by certain particulars, we can likewise say that those particulars are the same because they all produce images that all produce a second-order cognition of their sameness.

Some Indian realists maintain that this claim leads to an infinite regress. That is, in this respect all images of tables are the same because they produce the same effect, namely, second-order cognitions of their sameness. But since those second-order cognitions are all effects, they must be unique mental particulars. Thus, we must also prove that those second-order cognitions are the same. To do so, we must show that they all produce the same third-order cognition and an infinite regress ensues. In response, Dharmakīrti admits that the sameness of a certain set of images is constituted by their production of the same second-order cognitions. Nevertheless, the sameness of the second-order cognitions is not constituted by the sameness of their effects. Rather, they are all said to be the same in that they determine the first-order cognitions to be the same. This is an appeal to experience: the fact that the second-order cognitions include this determination of sameness is established by the apperceptive aspect of those second-order cognitions themselves.

It might appear that Dharmakīrti has opted for a realist theory of resemblance: certain particulars are the same in that they have the same causal capacity to produce images that in turn produce a determination of their sameness. But he rejects the notion of some shared causal capacity precisely for the reasons mentioned above: such an entity would have to be either the same as or different from the particulars in which it is instantiated and neither possibility makes sense.

Given that there can be no single entity that is the same in all cases, how then can we use this information that all tables, for example, produce the same effect? If we cannot even conclude that there is some repeatable causal capacity, then what will provide the commonality in all table-particulars such that we can use the expression 'table' for each one of them? Dharmakīrti answers that we need not find any repeatable entity at all. Instead, we need only admit that if all tables produce the same effect, this necessarily distinguishes them from all other particulars. In short, what is the same about all tables is that they are excluded from non-tables.

This move seems tantamount to calling a table a non-non-table and one might wonder why we should resort to this double negative: why not simply say that a table is a table? Although modern interpreters have taken this objection

seriously, Dharmakīrti noted that this qualm is misplaced for it fails to see how anti-realist ontological claims inform his semantics. Dharmakīrti's theory rests on the argument that repeatable entities are impossible. Since we undeniably experience particulars in such a way that we are able to classify them, our cognitions must group particulars into classes without having to pinpoint any repeatable entity. But since it is impossible to group particulars positively, we must do so negatively. The point here is that while we cannot posit any single, repeated entity that accounts for the fact that the particulars of a given class produce cognitive images that in turn produce the determination of their sameness, we are still able to distinguish between particulars that lead to that determination and particulars that do not.

The Mīmāṃsaka philosopher Kumārila (*fl*. *c*.625) responds that the reasoning employed is circular. That is, if Buddhists define 'tree' as the negation of 'non-tree', then one must be able to specify non-trees. Either this requires that one has already specified what trees are, or that one is somehow able to specify directly what non-trees are. In the former case, the theory of exclusion is superfluous since one can specify trees before excluding them from non-trees. In the latter case, one has specified what are non-trees without the negation of their complement. If this is possible in the case of non-trees, why should it not also be possible in the case of trees? The answer is the one stated above: we know that images are different by the apperceptive second-order cognitions that they induce. Nevertheless, we cannot specify any repeatable entity possessed by a certain set of images and not possessed by the set of all other images. We can only appeal to the difference and we use that difference to define both sets. Dharmakīrti suggests that if this theory is circular, then no theory of semantics will be able to avoid circularity.

Clearly, the theory of exclusion assumes some cognitive means of comparing images. Dharmakīrti notes that this process involves imprints (*vāsanā*) placed in the mind by previous experiences and that in the act of comparison those imprints become active. Another crucial factor enters into comparison: the intentions and expectations present in one's mind when one uses concepts and expressions. That is, since any cognitive image is necessarily unique it can be excluded from an infinite range of other images. For example, any table-image is unique and one can focus on its uniqueness by excluding it from all other images, even other table-images. If we wish to say that the particular which produced that image is a 'table', we ignore that image's difference from other table-images. Also, if we wish to speak of it as 'furniture' we widen our scope by ignoring its difference from chairs and such while maintaining its difference from all non-furniture, such as ping-pong balls. This process is a function of the goals, expectations and other disposition that we bring to any use of language and concepts. While accounting for the importance of dispositions in the determination of meaning, the theory of exclusion also allows Dharmakīrti to account for repeatability and reference without making any ontological commitments to universals. As far as the Indian realist account is concerned, it would seem that exclusions are universals instantiated in images. Hence, Dharmakīrti would face the same identity/difference objection that he levelled against the realists. To avoid this problem, Dharmakīrti resorts to the aforementioned distinction between ultimate and conventional reality. As a species of negation, exclusions cannot exist ultimately. Hence, no expression has any real referent. Nevertheless, in conventional terms exclusions can be said to qualify cognitive images and since any image is the unique effect of some particular, that causal link enables Dharmakīrti to claim that the particulars which cause images are the indirect referents of expressions. His semantic theory enables him to avoid the realist doctrine of universals when he claims that the information derived from language can lead to successful activity in the world.

Non-constructive rules of inference

For some theoretical purposes, generalized deductive systems (or, 'semi-formal' systems) are considered, having rules with an infinite number of premises. The best-known of these rules is the ' ω*-rule', or rule of infinite induction. This rule allows the inference of* $\forall n\Phi$*(n) from the infinitely many premises* Φ*(0),* Φ*(1),... that result from replacing the numerical variable n in* Φ*(n) with the numeral for each natural number. About 1930, in part as a response to Gödel's demonstration that no formal deductive system had as theorems all and only the true formulas of arithmetic, several writers (most notably, Carnap) suggested considering the semi-formal systems obtained, from some formulation of arithmetic, by adding this rule. Since no finite notation can provide terms for all sets of natural numbers, no comparable rule can be formulated for higher-order arithmetic. In effect, the* ω*-rule is valid just in case the relevant quantifier can be interpreted substitutionally; looked at from the other side, the validity of some analogue of the* ω*-rule is the essential mathematical characteristic of substitutional quantification.*

1 The ω-rule

In a standard formalized deductive system, the axioms form a decidable set of formulas (or, under Gödel-numbering, a recursive set of numbers), and each rule is a decidable relation between (conclusion) formulas and finite sets of (premise) formulas. (A set, or relation, is 'decidable' if there is an algorithm for determining whether a given item belongs to it, or given items stand in it.) A proof in the system can therefore be thought of as a tree of formulas, with the theorem to be proved at the root, axioms at the leaves, and at each node a formula which follows by a rule from its predecessors.

For some theoretical purposes, however, 'semi-formal' systems (generalized deductive systems) are considered, having rules with an infinite number of premises. The best-known of these rules is that called the rule of infinite induction, or the 'ω-rule'. This rule allows the inference of $\forall n\Phi(n)$ from the infinitely many premises $\Phi(0), \Phi(1), \ldots$ that result from replacing the numerical variable *n* in $\Phi(n)$ with the numeral for each natural number. About 1930, in part as a response to Gödel's demonstration that no formal deductive system had as theorems all and only the true formulas of arithmetic, several writers (most notably, Carnap) suggested considering the semi-formal systems obtained, from some formulation of arithmetic, by adding this rule.

An axiomatic system enriched with the ω-rule can, obviously, prove all the truths of first-order arithmetic: without loss of generality we may think of the atomic sentences of arithmetic as equations between terms made up out of numerals and the signs for addition and multiplication, so propositional logic and elementary algorithms (which can be simulated in standard axiomatic systems) suffice to prove all quantifier-free sentences of arithmetic, after which any true existential quantification can be inferred by the standard rule of existential quantifier introduction from one of its true instances, and any true universal quantification by the ω-rule from the set of all its true instances. (Proofs of true 'prenex' sentences (that is, those made up of a string of quantifiers followed by an atomic sentence) have this form exactly; other truths can be deduced from their prenex equivalents by standard means.)

If the language of the system goes beyond first-order arithmetic the situation is more complicated. Within a few years of its proposal, Rosser (1937) showed that the addition of the ω-rule to a standard system of higher-order arithmetic did not suffice to render the system complete. There are, however, some partial completeness results. Schütte (1960) showed that standard axioms and rules enriched with the ω-rule remain complete when the language of first-order arithmetic is supplemented with free variables for sets of numbers. Earlier, Orey (1956) had shown that any set of sentences of second-order arithmetic consistent with the ω-rule has an 'ω-model', that is, a model in which the second-order quantification (quantification over sets of numbers) can have a nonstandard interpretation in the manner of Henkin (1950), but in which the first-order quantifiers range over the genuine natural numbers. (Note that Schütte's result is that every sentence true in the standard model is a theorem of a certain theory, whereas Orey's is more analogous to completeness theorems for logics in specifying only a kind of model.)

The finite trees of formulas counting as proofs in a given formal system themselves form a decidable set of arrays, and can be Gödel-numbered; the set of (Gödel-numbers of) theorems of the system is thus defined by a Σ^0_1 formula, that is, a formula obtained from one expressing a recursive relation by existentially quantifying over

numbers (see Recursion-theoretic hierarchies). This is the general form of a definition of a recursively enumerable set, and, as shown most elegantly by Smullyan (1961), any recursively enumerable set can be represented by the set of theorems of a formal system. A proof in a semi-formal system can be represented by a set of numbers, so it is tempting to define the set of (Gödel numbers of) theorems of a semi-formal system by a formula starting with an existential quantifier over sets, by analogy with the definition of a recursively enumerable set by existential quantification over numbers.

But an ω-proof is a *well-founded* tree of formulas: it may have infinitely many branches, though each branch is only finitely long. So specifying just which sets of numbers correspond to infinite proofs would require a second quantifier over sets, and this would yield a Σ^1_2 formula as definiens. It is better to define the set of theorems directly, without reference to the infinite proofs, as the set of formulas belonging to every set which contains the axioms, is closed under the ordinary rules of inference, and contains a universal (numerical) quantification if it contains all its instances. This yields a Π^1_1 formula (a formula obtained by prefixing existential quantifiers over sets to a formula containing at most first-order quantifiers) as a definiens. Since Frege (1879) it has been standard to use a formula of this form in giving an explicit definition of an inductively defined notion, and sets definable by Π^1_1 formulas are sometimes called 'inductive' sets (see Aczel (1977) or Moschovakis (1974) for details). Any Π^1_1 set can be represented by the set of theorems of a semi-formal system.

Formal systems of arithmetic can be given an elegant formulation analogous to natural deduction or sequent-calculus formulations of pure logic, with the principle of mathematical induction taking the form of a rule of inference similar to the rules for the quantifiers. When this is done, it turns out that Gentzen's cut-elimination theorem for pure logic (1935) does not extend in its general form to arithmetic, but his later proof of the consistency of arithmetic can be seen as proceeding via a special case of cut-elimination that does hold. Kurt Schütte noted that it was possible to modify Gentzen's methods to prove a general cut-elimination theorem for various systems of arithmetic, provided that the cut-free proofs are allowed to employ the ω-rule. He and his colleagues have developed this into a useful tool for analysing formal systems of arithmetic: the complexity of the cut-free ω-proofs corresponding to proofs in a particular formal system turns out to be a measure of the strength of that system, correlating in particular with the class of number-theoretic functions whose totality can be proved in the system.

2 Related rules

Stronger infinitary rules, producing semi-formal systems of second-order arithmetic which are still incomplete but are stronger than those formed by adding the ω-rule to standard formal systems, have been studied by Mostowski (1961) and Enderton (1967). No satisfactory analogue of the ω-rule for introducing the universal quantifications over sets in classical higher-order arithmetic or set theory is possible because a formal language cannot contain terms for all the uncountably many sets in the standard model, but higher-order analogues of the ω-rule have been studied in the context of non-classical set theories. Schütte (1960) describes a type-free theory inspired by Ackermann; and Fitch, in publications starting in the late 1940s, obtained results closely related to those of later workers on the inductive semantics of type-free theories by studying semi-formal systems with rules similar to the ω-rule.

In the other direction, various weaker forms of the ω-rule have been studied. It is sometimes possible to prove in a finitary metatheory (or in a theory like Peano arithmetic used as its own syntactic metatheory) that all the instances of a certain quantification are provable in a formal system. A rule allowing the inference of a universal (numerical) quantification from the statement that all its instances are provable is sometimes called the 'formalized' ω-rule. Such a rule, unlike those discussed above, is of finitary character; added to a formalized system of arithmetic it amounts to a kind of reflection principle. Feferman (1962) showed that every true sentence of first-order arithmetic is provable in some formal system in a transfinite hierarchy of systems obtained from a standard axiomatic system by iterated addition of reflection principles. (Much earlier, Hilbert (1931) had proposed a restricted version of the formalized ω-rule in what seems to have been an attempt to get around Gödel's incompleteness theorems.)

A somewhat related idea is the 'constructive' ω-rule: take $\forall n\Phi(n)$ to be a theorem if there is a recursive function assigning to each natural number (the Gödel number of) a formal proof of the corresponding instance of $\Phi(n)$. Despite the name, this is a non-constructive rule, since it is not in general a decidable matter whether or not there is a recursive function of the sort required: Shoenfield (1959) shows that all truths of first-order arithmetic are

provable with it.

Non-monotonic logic

A relation of inference is 'monotonic' if the addition of premises does not undermine previously reached conclusions; otherwise the relation is non-monotonic. Deductive inference, at least according to the canons of classical logic, is monotonic: if a conclusion is reached on the basis of a certain set of premises, then that conclusion still holds if more premises are added.

By contrast, everyday reasoning is mostly non-monotonic because it involves risk: we jump to conclusions from deductively insufficient premises. We know when it is worthwhile or even necessary (for example, in medical diagnosis) to take the risk. Yet we are also aware that such inference is 'defeasible' - that new information may undermine old conclusions. Various kinds of defeasible but remarkably successful inference have traditionally captured the attention of philosophers (theories of induction, Peirce's theory of abduction, inference to the best explanation, and so on). More recently logicians have begun to approach the phenomenon from a formal point of view. The result is a large body of theories at the interface of philosophy, logic and artificial intelligence.

1 Sources of non-monotonicity

A relation of inference is 'monotonic' if the addition of premises does not undermine previously reached conclusions; otherwise the relation is non-monotonic. Theories of non-monotonic inference locate the source of non-monotonicity in various forms of calculated risk-taking in the course of seeking information. Many kinds of reasoning involving 'degrees of belief' provide familiar examples. Suppose that a set *A* of assumptions raises the credibility of an event described by a sentence *b* above a certain threshold. (Lower case letters will stand for sentences in a given language, upper case letters denote sets of sentences.) Then it is quite possible that the credibility of *b* falls below that threshold if further assumptions are added to *A*. Thus, while one may be prepared to accept *b* on the assumptions *A*, one may prefer to remain agnostic about *b* given additional information. Credibility here may be measured by ordinary probability or by more general measures, such as Shackle's (1979) non-additive degrees of belief (where the credence of mutually exclusive and jointly exhaustive alternatives need not add up to unity). Indeed, most advocates of non-monotonic formalisms insist that they model a wider class of phenomena than can be captured by ordinary probability functions.

A particularly simple source of non-monotonicity is the 'closed world assumption' (CWA). With respect to a given collection of data about some subject matter it states that the collection is complete; that no relevant information is left out. Hence, if *a* is not part of the collection, it is safe to assume $\neg a$. Since *a* may be derivable from a larger set of data, derivability under the CWA is non-monotonic. The CWA is behind the treatment of 'negation as failure' in Prolog ('Programming in logic', a programming language): Prolog derives $\neg a$ from a set of data *D* just in case a query for *a* given *D* fails. (Caution: *a* must be of a suitably simple syntactic kind. For complex sentences, negation as failure is a delicate and potentially hazardous matter.)

Another source of non-monotonicity is the licence to draw from a pool of presumptions ('defaults') as long as these are 'safe' to use (that is, consistent). For example, if one is told that tea is served, one will naturally act on the presumption that it is served plain or with milk and/or sugar. That presumption may become unsafe as additional information is supplied (such as that tea is served with brake fluid or salt).

Default logic (Reiter 1980) is one of the first and most influential theories responding to this source of non-monotonicity. It serves well as a principal example of a non-monotonic logic because it exhibits very clearly three characteristic features of almost all theories of non-monotonic reasoning: first, closure under rules with premises that require tests for non-derivability ('non-Horn' rules); second, a non-unique process of extending premises using defaults; and third, some method for reducing the multitude of extensions and for specifying a univocal set of conclusions.

A 'default theory' (D, A) (giving rise to a default logic) consists of a set *A* of premises (or 'facts') and a set *D* of default rules ('defaults' for short), each of the form

(1) $(B : C) \Rightarrow a.$

These rules are to be read as follows: infer *a* from *B* unless *C* is inconsistent with what can be known by default on

the basis of *A*.

A similar and, under certain conditions, equivalent way of expressing defaults is by modal formulas such as

(1′) $\Box b \wedge \neg\Box\neg c \rightarrow a,$

as in Moore's (1985) auto-epistemic logic, where $\Box a$ may be read '*a* is known'.

The rule (1) is non-Horn, since the 'unless' clause must be verified by showing that no contradiction can be derived from *C* together with the closure of *A* under the default rules.

Closing the premises *A* under the default rules in *D* issues in an extension of the default theory (D, A). More precisely, let $\Sigma = (S_0, S_1, \ldots)$ be a sequence of sets of formulas with $S_0 = A$, let *S* be the union of all its members, and let each S_i in Σ be such that

$$\begin{aligned} S_{i+1} = \{a\text{: there is a default } (B : C) \Rightarrow a \text{ in } D,\\ B \subseteq Cn(S_i) \text{ and}\\ C \text{ is consistent with } S\} \end{aligned}$$

(where *Cn* denotes the operation of generating the deductive consequence of a given set). For each such sequence Σ, $Cn(S)$ is called an 'extension' of the default theory (D, A).

To see how a single default theory (D, A) gives rise to a multitude of extensions, let $A = \{a\}$ and consider a set *D* of two defaults,

(2) $(a : \neg b) \Rightarrow c$
(3) $(a : \neg c) \Rightarrow b$

If we first close *A* under (2), we obtain a set A_1 containing *c*, so *b* cannot be inferred using (3). If we first close *A* under (3) we obtain a set A_2 containing *b*, so *c* cannot be inferred using (2). Thus, the result of extending a set of premises ('facts') by using default rules depends on the order in which the rules are applied. In general there are many extensions of a set of facts under default rules; sometimes there are none (Poole 1994: §7).

The multiplicity can be resolved by intersecting a set of selected extensions. There are three basic options for selecting: according to the 'sceptical' (full meet) solution, all extensions should be selected; the 'brave' (maxi-choice) approach recommends selecting a single extension; and the 'cautious' (partial meet) approach is less committal in requiring only that some extensions be selected. In each case a set of premises *A* is said to entail a conclusion *b* by default *D* just in case *b* follows deductively from the intersection of all selected extensions of *A* under *D*. How should one select among possible extensions? Some approaches recommend that the basis should be syntactic information about the applied defaults: for example, that extensions generated by more specific defaults should take precedence over those generated by more high-handed ones. Others assume that defaults are to be ordered, either by a qualitative preference ranking or by a numerical assignment of degrees of belief.

2 Patterns and models of non-monotonic inference

Inference is 'defeasible' if new information may undermine old conclusions. Formal theories of non-monotonic reasoning differ greatly both as to the kind of defeasibility they focus on and as to their chosen level of generality. They also differ, at first sight, from what are typically referred to as 'logics'. Still, the term logic is appropriate because all these theories can be used to specify a relation in some formal language which exhibits many of the patterns usually associated with relations of inference.

It is not enough to characterize defeasible inference negatively by the possible failure of monotonicity. We also need to ask: which conditions are compatible with defeasibility and which conditions should be satisfied by any relation of inference? These questions point towards continuing the abstract study of consequence relations (or operations) initiated by Tarski (1930). By abstracting from the particular ways in which inference relations are generated we turn to properties they may share.

Let $Cn(A)$ stand for the set of classical and $C(A)$ for the set of defeasible consequences of some set *A*. Among the more stable properties for *C* that have emerged are the following:

to A$\subseteq C(A)$(inclusion) $C(A) = C(C(A))$(idempotence) If $A \subseteq B \subseteq C(A)$ then $C(A) = C(B)$(cumulativity) $Cn(A) \subseteq C(A)$(supraclassicality) $C(A) \cap C(B) \subseteq C(Cn(A) \cap Cn(B))$(distribution)

In the presence of the other conditions, cumulativity is equivalent to the slightly more perspicuous: from $A \subseteq C(B)$ infer $C(A \cup B) = C(A)$. The properties of *C* may be recast in terms of a relation $A \mid\!\sim b$, defined to mean $b \in C(A)$. For example, cumulativity combines the classical principles of cut,

$$\text{If } (\forall b \in B) A \mid\!\sim b \text{ and } A \cup B \mid\!\sim c, \text{ then } A \mid\!\sim c (\text{cut})$$

with a cautious form of monotonicity,

$$\text{If } (\forall b \in B) A \mid\!\sim b \text{ and } A \mid\!\sim c, \text{ then } A \cup B \mid\!\sim c. (\text{cautious monotonicity})$$

Inference operations (and their associated relations) satisfying the first three conditions are called ‘cumulative’; if they also satisfy the last two conditions, they are called ‘classically cumulative’. Note that although the above list describes the common core of various theories of non-monotonic inference, theories based on high probability rules for acceptance are not among them. If $A \mid\!\sim b$ is defined to hold just in case the probability of *b* given all members of *A* reaches a certain threshold, then $\mid\!\sim$ satisfies neither cut nor cautious monotonicity, nor can $\mid\!\sim$ be both idempotent and supraclassical; for that would entail the objectionable left absorption principle $C = CnC$. (Objectionable because of ‘lottery paradoxes’ where both *a* and *b* are accepted, while their logical consequence $a \wedge b$ is not (see Kyburg 1961).) Still, high probability accounts of $\mid\!\sim$ can be made to score better on the above properties, if the probability required for acceptance is pushed high enough, that is, infinitely close to unity. Such accounts have been developed by Adams (1975) and Pearl (1988).

Cumulative inference can be characterized in terms of *preferential models* (see Shoham 1987; Kraus, Lehmann and Magidor 1990; Makinson 1994). These consist of a set of ‘states’ ordered by some relation $<$ and a mapping $|\ |$ assigning to each sentence a set of states. Intuitively, the mapping takes a sentence to a state just in case the sentence truly describes the state, and the relation $<$ orders states with respect to their ‘extravagance’ (conversely, ‘naturalness’). For example, a state in which tea is served with a dash of brake fluid is less natural (more extravagant) than a state in which tea is served with salt, which in turn is still less natural than serving tea with sugar or with milk or with both. The most natural states are the states we can expect to obtain unless there is evidence to the contrary.

If $|a|$ is the set of all states at which *a* holds, then the minimal elements of $|a|$ under $<$ represent the most natural (‘preferred’) ways for *a* to be true. The condition of ‘stopperedness’ (sometimes called ‘smoothness’; see also the ‘limit’ assumption in Lewis 1973) requires that there always are minimal elements.

For each set *A* of sentences, let $|A|_<$ denote the set of minimal states at which all sentences in *A* hold. Then *A* *preferentially* entails *b* just in case $|A|_< \subseteq |b|$. In contrast to ordinary entailment, preferential entailment restricts the domain of quantification: not all possible but only the most natural ways in which all elements of *A* can be true are considered. Since a most natural way for *A* to be true may not be a most natural way for $A \cup B$ to be true, preferential entailment is not monotonic. To illustrate: we may find that all most natural ways of making the sentence ‘tea is served’ true will please someone in the room. But that finding may well be undermined, if we move to considering all ‘natural’ ways of serving tea with brake fluid.

It can be shown that (stoppered) preferential entailment is a cumulative inference relation and that every cumulative inference relation can be presented as a relation of preferential entailment. (For the representation results mentioned here see Makinson 1994: §3.4.) The condition of stopperedness guarantees that preferential entailment will be cautiously monotonic. (To see how cautious monotonicity may fail in non-stoppered models let the states be indexed by the natural numbers and let s_m be more natural than s_n just in case *m* is greater than *n*. Consider three sentences a, b, c such that *a* holds everywhere, *c* fails everywhere and *b* holds at the first state only. Then $|a|_< = \emptyset$ because there is no most natural state for *a*. So, on the one hand we have both $|a|_< \subseteq |b|$ and $|a|_< \subseteq |c|$ vacuously. On the other hand, there is exactly one state - namely the first - that satisfies both *a* and *b*. Hence, $|\{a, b\}|_<$ - having the first state as its (only) member - cannot be contained in $|c|$ since the latter was assumed to be empty.)

If the mapping $|\ |$ is classically well-behaved (that is, satisfies the equations $|a \wedge b| = |a| \cap |b|$ and $|\neg a| = \overline{|a|}$), then each state will be closed under classical consequence whence preferential entailment will be supraclassical. Moreover, it will also be distributive and thus satisfy the conditions for being classically cumulative. Conversely,

each classically cumulative inference can be represented as preferential entailment in preferential models that respect the truth-functional connectives.

Supraclassicality is a rather common property of non-monotonic reasoning. It gives formal expression to the idea that such reasoning goes beyond what can be inferred 'safely' (deductively) from a given body of knowledge. However, some theories of non-monotonic inference (like those based on defeasible inheritance nets or on reason maintenance systems) fail to fully extend classical logic because they operate in impoverished fragments of classical languages. Such restrictions are usually introduced for computational reasons; they are not based on principled objections to supraclassicality.

Note also that in so far as non-monotonic logics are supraclassical, they are not rivals but extensions of classical logic. This sets them apart from certain other logics which fail to be monotonic, such as relevance, linear and many paraconsistent logics. These logics are *sub*classical and their source of non-monotonicity is different, having nothing to do with 'risk-taking'.

3 Related work

A sentence *b* may be (defeasibly) inferred from a set *A* in the light of background assumptions *B* just in case *b* follows logically from *A* together with as much of *B* as is compatible with *A*. The right-hand side of this equivalence can be seen as involving a step of belief change: from the background beliefs *B* to a *revision* of *B* so as to accommodate *A* (with a minimal amount of change). Belief revision and defeasible inference thus appear to be two sides of the same coin.

The correspondence between belief revision and non-monotonic reasoning has been investigated in depth by Gärdenfors and Makinson (1994). In contrast, Levi (1995) argues that the correspondence can only be partial because the sole purpose of belief revision is to accommodate belief-contravening evidence. Such accommodation obeys a maxim of minimal change. But in so far as non-monotonic reasoning also covers ampliative inference, it must go beyond the maxim of minimal change governing belief revision. Hence, according to Levi, properties of non-monotonic inference as generated by belief revision on the one hand and as generated by ampliative inference on the other hand cannot be expected to coincide.

There is a close relation between counterfactual conditionals and belief revision via the 'Ramsey test': accept a conditional 'If *a* were the case, then *b* would be the case' in a state of belief *A* just in case you would accept *b* if *A* had to be revised so as to contain *a*. Given the correspondence, noted in the last paragraph, between belief revision and non-monotonic reasoning, one expects - and will not be disappointed - to find similarities between counterfactuals and non-monotonic reasoning.

A more direct route to such similarities is opened by comparing preferential models with the Stalnaker-Lewis semantics for counterfactuals (see Counterfactual conditionals §§3-4). In this semantics a counterfactual is pronounced true in a 'world' *w* just in case the consequent is true in all the closest possible worlds (that is, those worlds which depart as little as possible from *w*) that make the antecedent true. There is an obvious similarity between the condition for evaluating preferential entailments and that for evaluating counterfactuals: not all antecedent-worlds are examined but only those that are minimal under a certain relation. But there are also differences. Because each model for counterfactuals is equipped with as many relations of closeness as there are worlds to be close to, counterfactuals can be evaluated (differently) at single worlds. By contrast, preferential models have only one relation; accordingly, preferential entailments are assessed not with respect to single worlds but only in a model as a whole. It is a controversial matter how to interpret such subtle differences (see Makinson 1993): whether preferential entailments are essentially valid counterfactuals frozen at the first degree (that is, with the conditional connective joining truth-functional formulas only) or whether the differences are more substantial.

Normative epistemology

There are three kinds of normative work in epistemology. The first is the provision of epistemic advice, which offers guidance towards improving the cognitive condition of an individual or community. This advice often concerns science. Philosophers in the tradition of Francis Bacon have sought to identify and advocate proper forms of scientific research and explanation. More generally, according to some philosophers, a principal epistemological task is that of finding and recommending ways to improve the whole range of our individual and collective cognitive activities.

A second kind of epistemology is classified as normative because evaluative concepts figure in explanations. For example, A.J. Ayer explains knowledge partly in terms of having a right to be sure. Other evaluative notions enter into work in this category, such as intellectual duties, responsibilities and virtues. Some of these are specifically ethical notions; some are non-ethical evaluative notions such as proper cognitive functioning and intellectual excellence.

Epistemic concepts such as justification and rationality appear to be normative, or at least evaluative, in a way that contrasts with purely desciptive concepts. One tendency in naturalistic epistemology is to seek either to explain away this appearance or to reconcile it with a scientific worldview. Non-naturalistic efforts in epistemology commonly find no reason to undertake this project, and are consequently often counted as normative. Most historical epistemology is normative by this standard.

1 Advisory epistemology

Francis Bacon and René Descartes are among the prominent historical philosophers who advocated methods of cognitive improvement. Bacon (1620) defended methodological departures from the scholastic intellectual traditions that prevailed in Europe in his time. The investigative practices that Bacon recommended constituted early modern scientific methodology (see Bacon, F. §§4-8).

Descartes (1701) elaborated a system of rules to guide inquiry. His most characteristic enterprise was a search for certainty in his beliefs. He advocated a method of doubt for achieving certainty. In Descartes' view, beliefs that withstand the strongest reasons for doubt are certain. Such beliefs are distinguished by being clearly and distinctly perceived. His rules are designed to facilitate achieving this (see Descartes, R. §4).

In the twentieth century, Alvin Goldman among others has supported advisory projects for epistemologists. Goldman (1986) has championed 'epistemics': an alliance between epistemology and cognitive psychology. Epistemologists contribute to the joint effort by identifying epistemically desirable magnitudes that apply to belief formation process types, such as the truth-to-falsehood ratio of the doxastic output of a process type. Psychologists determine the degree to which actual psychological processes exemplify these magnitudes. They also contribute to epistemics by studying how, and to what extent, our cognitive capacities allow the magnitudes to be exemplified to other degrees. In light of such psychological findings epistemologists engaged in epistemics propose strategies for effecting cognitive improvements.

Advisory epistemology has problematic characteristics. For one thing, philosophical thought does not seem to constitute a suitable preparation for recommending successful ways to conduct empirical science. Effective ways to learn the contingent facts that are the subject matter of science seem themselves to be matters of contingent empirical fact. Bacon and other philosophers of science may well have happened to acquire the empirical information useful in making helpful recommendations in this area. But the actual efficacy of any given empirical research strategy seems to be an empirical question rather than a philosophical one.

More fundamental difficulties affect epistemological advice on all topics. These problems concern whether there is some distinctive epistemic standard, and whether there is any general justification for recommending cognitive conditions or processes that have some positive epistemic status. Epistemic advice seems to include identifying and asserting effective techniques for gaining various epistemically favourable outcomes, such as reasonable beliefs, justified beliefs, true beliefs, and knowledge. This multiplicity of positive potential outcomes does not always coincide, and that leads to the first problem. Note that it might be feasible to get someone to believe some difficult truth for a bad reason and feasible to give them good reason to believe the negation of that truth, but not

feasible to get them to believe the truth for a good reason. When there is some such competition between apparently valuable epistemic states, what is ‘epistemically advisable’? A single overriding ranking of epistemic outcomes would answer this sort of question. But does such a ranking exist, and if so, why does it override?

The other fundamental problem concerns justification for issuing any epistemic advice. Is some such advice somehow justified even when the advised outcome is not sought and is not an effective means for attaining anything that is sought? For instance, suppose that a friend is interested in forming a belief about what fraction of the inhabitants of Tibet are Buddhists. It might seem to be sensible epistemic advice to recommend forming this belief on the basis of a large and randomly selected sample. Believing on this sort of basis may well give such beliefs a relatively high truth-to-falsehood ratio. Does this make that basis ‘epistemically advisable’? Suppose that a friend wants to form a fanciful belief on the topic, with no concern for its truth. If so, what justification would there be for offering the hypothesized advice? Or suppose that the friend seeks certainty and nothing less. The advised procedure will not yield that. Would the same recommendation be apposite, and if so, why?

Recommendations can be justified in various ways. Advice can be justified for the sake of meeting several sorts of standards, such as moral ones, legal ones and goal-oriented ones. So various beliefs and inferences might be morally, legally or instrumentally advisable. But there seems not to be any unified notion of ‘cognitive betterment’ that could provide some distinctively epistemic standard justifying the issuing of doxastic advice (see Scientific method).

2 Evaluative epistemology

In a tradition which is traceable to John Locke, some philosophers have theorized about epistemic notions in plainly evaluative terms. One line of thinking, directly initiated by Locke and recently represented by Roderick Chisholm, appeals to intellectual duty. Another approach, stemming from Cartesian and Lockean origins and present in recent work by Laurence BonJour (1985) and Hilary Kornblith (1980), explains a kind of epistemic justification for belief in terms of responsible doxastic conduct.

Criticism has been offered of requiring any such duty fulfilment or responsible conduct in order for believing to have some positive epistemic status. Some objections are based on the assumption that epistemic duties or responsibilities are limited by our ability to comply with them. A common sort of objection adds the premise that we seldom if ever have control over what we believe. These assumptions together imply that we seldom if ever have such duties or responsibilities to believe otherwise than we actually do. Yet believing otherwise frequently does have some positive epistemic status. Thus dutiful or responsible doxastic conduct is not required for having this status.

There is a reasonable reply to this criticism. It is doubtful that all duties are limited by the ability to comply with them. Duties from various sources seem to exceed this limit. Political entities appear to impose legal duties beyond the abilities of their citizens always to comply. The duties taken on by agreeing to perform a job with certain assigned responsibilities may turn out not to be feasible to accomplish. So the general principle that duties can always be met seems unacceptable. Even within the sphere of purely ethical duties, it has been credibly argued that obligations can exceed abilities. Consequently, the principle that epistemic duties in particular are limited by ability stands in need of some special defence.

Alvin Plantinga (1993) has offered a different criticism of a reliance on intellectual duties in a theory of knowledge. Plantinga’s topic is a theory of warrant. ‘Warrant’ is his term for a magnitude the bearing of enough of which by a true belief constitutes a case of knowledge. Plantinga objects to the thought, derived from work by Chisholm, that believing a proposition as a result of trying one’s best to fulfil one’s epistemic duties is sufficient for being warranted in the belief to some significant extent. Plantinga describes the following case. Paul is given by a malicious demon a nearly overwhelming tendency to believe that whenever it sounds to him as though a church bell is ringing what he is hearing is orange in colour. All who are around Paul have been given this same tendency. Plantinga contends that, by acceding to this strong inclination when hearing a church bell sound and believing that what he hears is orange, Paul would fulfil his epistemic duties. Yet this belief would have little or no warrant for Paul. Plantinga concludes that complying with intellectual duty is not sufficient for being significantly warranted in the resulting belief.

There is a promising reply to this objection. It can be maintained that having even a nearly overwhelming tendency

to believe something does not generate an intellectual duty to believe it. What intellectual duties require is conformity to epistemic reason. A sound and a colour are conspicuously diverse. In Plantinga's example Paul is ascribed no *reason* for thinking that the two go together. So, intellectual duty calls for Paul to refrain from forming the colour belief. He would thereby respond rationally to the manifest lack of any evidential connection with the sound. He has no epistemic ground, and hence no duty, to give in here to a powerful but unreasonable impulse. Thus, this sort of case does not seem to pose an insuperable problem for the claim in question that complying with intellectual duty is sufficient for having significant warrant.

3 Non-naturalistic epistemology

Naturalism in epistemology has no widely accepted definition. Naturalistic epistemologists variously ally themselves with science in ontology or method. They tend to seek explanations of epistemic facts that employ properties with actually or prospectively good scientific credentials, such as causal relations and statistical probabilities, and they tend to classify the epistemological claims that they make as empirical rather than a priori (see Naturalized epistemology). Sometimes it is counted as adequately naturalistic to postulate entities that have some suitable sort of ontological dependence on physical reality, whether or not the postulated entities themselves play a role in physical science (see Supervenience).

It is notoriously difficult to see how ethical features such as intrinsic goodness and moral obligation can be part of the sort of reality that science describes. Like such ethical evaluations, some epistemological categories seem to resist assimilation to a scientific worldview. Several of the main epistemological characterizations, such as 'justified', 'rational' and 'reasonable', seem to make comparably evaluative appraisals of the mental states or processes to which they are applied. It is comparably unclear how such epistemic attributes of belief and reasoning fit into the world of natural science. Naturalistic epistemologists characteristically attempt to clarify this fit or eliminate the recalcitrant epistemic features.

Other epistemologists do not make this attempt. At one non-naturalistic extreme there is work like that of Alvin Plantinga, who argues that God plays a role in the nature of warrant. Plantinga conceives of warrant in terms of properly functioning cognitive mechanisms. He argues that only the intentional design of these mechanisms by God is adequate to explain their proper function. This sort of view relies on a defiantly non-naturalistic ontology.

Many non-naturalist epistemologists simply theorize in terms of whatever concepts they find adequate to their theoretical tasks, without paying heed to naturalistic constraints. For instance, a coherence relation among propositions figures in some theories of epistemic justification, and often no effort is made to square the existence of this coherence relation with a scientific ontology (see Knowledge and justification, coherence theory of).

Non-naturalistic methodology is common in epistemology. Explicit appeals are made to a priori considerations in defence of epistemological theses, typically by claiming support by appeal to intuitive judgments about hypothetical cases. This methodological departure from natural science marks the work as non-naturalistic.

Some epistemologists thus do not abide by the ontological and methodological constraints that are characteristic of naturalism. This is unproblematic to the extent that these constraints are inadequately defended. Notably, they seem to have no credible defence when applied to the analogous field of pure mathematics. To ban from mathematical research a priori considerations or ontological commitments beyond the foreseeable domain of natural science would abolish the discipline. This would be unwise. Unconstrained mathematics efforts yield some of our clearest and most secure knowledge.

It seems similarly unwise to burden epistemological inquiry with naturalistic constraints. Much non-naturalistic epistemological work is relevantly similar in method and subject matter to mathematical work that yields knowledge. Although established results are rare in epistemology, the example of mathematics shows that we have good reason not to blame the paucity of such success on a violation of naturalistic constraints.

Norms, legal

A legal norm sets a standard of behaviour. As a norm, it thus can remain in existence even though it is broken. Norms can be distinguished from causal laws which need to be reinterpreted if an exception is found. Linguistic signals help us determine what the norm is. Thus 'ought', 'must', 'shall', 'have to', 'right', 'wrong', 'good', 'bad', and so on, characteristically belong to the statement of norms, whereas words like 'is', 'are', 'were', 'will be' 'possible', 'impossible' tend to show descriptive rules. These linguistic signals reflect a difference, they do not constitute it. There are many counterexamples: thus 'swimming is forbidden' and 'we ought to be at the col now' express normativity and description respectively.

Whatever is for someone a standard for their conduct is normative for them. One might say that the idea stems from the notion of measurement. That we 'run the rule' over someone or 'get the measure of them' stems from the idea of measuring, of imposing a standard on them or on oneself.

Where does the legal norm stem from? There are two main views: the practice theory holds that norms are expressions or articulations of people's behaviour; the interpretive theory holds that norms are not connected to behaviour in the way the practice theory holds but are the means whereby we make sense of such behaviour. But the connection between the two groups is much closer than appears at first sight.

1 Normativity and description

The law prohibiting murder seems both different from, and more mysterious than, the law of gravity. Why? One can break the former and it will still be valid and in existence but we still have to follow it. There is still something that constrains us, that binds us. The fact that the murder rate has gone up will not be taken as evidence that it does not exist. However, if objects started to float away into space then the law of gravity would have to be revised, an exception to the scientific law must modify it. The law cannot be broken.

We can explain this by looking at the difference between 'doing something as a rule' and 'having a rule about something', as Hart posed it (1961). Take the behaviour of a group of cars at a traffic intersection. We could say that they stop at the red traffic lights 'as a rule'. This would imply that there is a certain regularity of behaviour but that if there is a departure from it this will be merely something unusual, a departure from the average. Scientific laws stem from this sort of observation. They generalize into a rule what normally happens, what people do 'as a rule'. This will take the form of some causal explanation about the nature of the world. But we can give another explanation. We may say that the cars' behaviour is governed by the Road Traffic Act. There is a difference between that law and the causal one we observed earlier. The former is provisional. If we find that cars do not stop at red lights any more that means that our causal law is invalid and we have to amend it. Whereas the fact that cars do not stop at red traffic lights does not make the Road Traffic Act invalid. We ought to obey even if we do not. We are not looking at the generalization of 'as a rule' behaviour. Rather we are looking at a standard of behaviour, departure from which would not just be seen as unusual but as a reason for criticism. Here there is a prescription as to what behaviour is required. In the first case there was not. The former is a normative law while the causal law is descriptive.

We now turn to asking what the legal norm is and how we can recognize it. This is closely tied up with where normativity itself comes from. The question as to whether something is a religious norm, a moral norm or a legal norm is mainly a formal question. Thus, as we will see below, the basic question when looking at the legal norm is to understand its normativity.

2 The practice theory

We may first of all think of the norm as stemming from simple iteration; that is, what is done once will be done again, and will through repetition induce expectation, in this way producing normativity. Thus, *per* Hayek (1969), normativity comes from custom which is generalized into abstract and general rules. This is the best way because it reflects that what people should have as standards of behaviour is what over a long period of time they have done. What is important here is the iteration. Something happening over and over again is what imparts normativity. The legal norm is the abstraction of that.

Hayek's theory is a modern version of older theories that stressed custom as the source of law. John Austin thought that custom missed out the element of the will: the legal norm was a species of command. The norm is the imposition of the will of one person, who sets the standard of behaviour, on another. Thus Austin (1971) gives a definition of law (the legal norm) as the command of a sovereign backed by a sanction. Laws are thus a species of commands, directed by sovereigns to their subjects. They are an exercise of political will or power and necessarily involve the imposition of sanctions in the case of disobedience. But, behind obedience to this will, there re-enter descriptive regularities of custom and usage in the shape of what Austin calls habit.

Austin defines the sovereign as the 'political superior' towards whom the population exhibits a 'habit of obedience'. As a political superior the sovereign's power and authority is based in social practices and in the social fact of habitual obedience - the social source of law. The normativity of law, one might say, comes ultimately from the barrel of the gun which people habitually obey (see Sovereignty §2).

H.L.A. Hart is more complicated. He wants to reject the command theory but still claim that normativity comes from social practice. For him norms are not merely commands but can be seen as rules. The key is in his famous distinction between being obliged and having an obligation. Austin's version of the legal norm misses the idea of obligation. It can be best likened to the gunman who demands money from you. You are obliged to give it to him, but only as long as he is pointing the gun at you. The legal norm lasts after the gunman has gone. It is something more than merely a habit of obedience to some commander. Habits refer only to the external regularities of behaviour. By contrast there is an internal aspect in the case of rules of conduct shared by members of a social group. This depends upon the attitude (a critical reflective attitude) of insiders of the group. For them a certain regular pattern of behaviour is not merely observable regularity. It is a standard for the criticism of conduct which contravenes the pattern in question. This is expressed in the idea of obligation. This comes both from people's behaviour and from their attitude. To say that someone has an obligation implies two statements, a cognitive statement that there are observed regularities and a volitional one that people have the critically reflective attitude to that regularity.

The above are examples of a general way of seeing the legal norm that can be called the practice theory; the norm must be inextricably connected to real action in the world. Normativity then stems from people's practices. But this idea has also been criticized. One can always intelligibly ask of a practice whether one ought to follow it and therefore the norm cannot be constituted by the practice. For Hart this does not make sense. If there is a critically reflective practice it would be unintelligible for someone within that to ask whether they ought to follow it. It would be like asking if the standard metre bar in Paris (by which the metre used to be defined) is really a metre. However, for Kelsen (1960) it would make sense because, in following this practice, we assume that is how a metre ought to be defined. And this explains why for Kelsen the *Grundnorm* (the norm from which all other norms in the system get validity) has to be presupposed to be valid while the equivalent for Hart (the ultimate rule of recognition) just is.

3 The norm as interpretation

For Kelsen, then, the legal norm is the meaning of an act of will. It is not the police waving the car down but the meaning of the police's act as saying that 'you ought, by the authority vested in me by the Road Traffic Act, to stop' that is the legal norm. The content of the norm must not be confused with its physical expression. But behaviour still has some importance in the sense that one can only derive a legal norm in the context of efficacious behaviour. It only makes sense to understand the physical activities that constitute the parliamentary process as law-making behaviour when people by and large do treat them as such and obey them.

In separating the norm more and more from behaviour in the physical world, we can see the legal norm as a standard of judgment. Thus Dworkin (1986) attacks the rule-based theory of law and sees principles and latterly rights as being the key to the legal norm (see Dworkin, R.). But where do they come from? In his interpretivist turn we see the return of practice. For the rights are our interpretation of the community's practice. We can thus say that they are the meaning of the community's practice. Now this sounds remarkably like Kelsen's version of the legal norm. For it is the meaning of the practices that is important and that is what gives us the rights. If however we think of the practices as constituting the rights then we see something more like Hart, even though Dworkin, ironically, started his professional life by attacking Hart. The meaning of the practices is locked into the practices that we do and we cannot go beyond them; the legal norm (in the form of rights) comes from our interpretation of

them. For him too it makes no sense for someone inside the practice to question its validity.

This shows the difficulties of making a rigid separation between the normative and the descriptive, at least in the way that the normative is generated. Because, even for Kelsen, it makes no sense to generate a meaning except in the context of by-and-large efficacy. We have a sort of spectrum then. The norm is custom or habit and is thus fully expressed in the practice or, more complicatedly, in a critically reflective practice. Kelsen separates the critically reflective from the practice in order to separate the meaning of the norm from the act of will that generates it. But that separation does not work totally because we can, as Dworkin does, construct the hermeneutic circle and see the meaning as constituting the practice (see Common law).

That one cannot get totally away from practice can also be seen in another critic of the practice theory, Joseph Raz (1979). For him the legal norm is a species of reason for action, specifically an exclusionary or content-independent reason for action. We can explain it in this way. Someone is telephoned late at night by a friend and offered the chance of a speculative but potentially highly lucrative investment. The only drawback is that they have to make up their mind immediately. Knowing he is a bit drunk and tired, and thus not trusting his judgement, what should he do? He could make the decisions on the balance of all the reasons *pro* and all the reasons *contra* including the reason that he is tired and a little drunk. He could, on the other hand, say that he makes it a rule not to take investment decisions late at night. The former way of doing it would be to make the judgment on the balance of reasons. The latter would use the rule ‘do not take investment decisions late at night’ as a reason for excluding consideration of the investment decision on the balance of reasons, even though that decision might be to make the investment. His decision would operate at a second-order level in respect to the reasons of substance as to whether to take the investment decision or not. It would thus be an exclusionary reason or a content-independent reason. We would have a reason for not thinking about the substance of the case because of this second-order reason.

But where does that reason come from? From where is, in Raz’s terms, the ‘legal point of view’ generated? In the end we can find the generation of these only in the institutions of law as they are. We thus see that the standard criticism of natural law theories that they conflate the descriptive with the normative is, in some sense, replicated among other, more positivistically inclined, legal theorists. They both face similar problems - where is normativity generated from?

John Finnis (1980) in his natural law theory sees the legal norm, on Razian lines, as an exclusionary reason. But it is a reason for action because it instantiates the objective values of the universe, more specifically the values of practical reason and human sociability, and it is these that generate legal norms. But how do we know these values? It is not our drives which are the goods. The good of life is not to be reduced to our sexual drive. We are not animals. Rather it is the way in which the drives are transformed through our intelligent understanding that makes them basic values. For example, our drive to survive is not what the good of life is. Survival is not a basic good. Rather it is our understanding of this which enables us to see that we should not survive at all costs and that is not what the good of life means. The problems here are the same as they are in positivist theories.

For Finnis legal norms instantiate moral norms and are *determinationes* of ultimately self-evident values. We can then say that most theories of the legal norm see it as in some way connected to the things that people do. The ’ought’ comes in some way from causal regularities in the world, as bearer, constituter or condition of the norm. So we can see that the norm comes in the end from people’s behaviour or their understanding of it. We ought to do X because in some way we *do* do it. And this appears true even in apparently metaphysical accounts such as those of the natural law. Normativity then is something connected to what people do and not something mysterious at all (see Natural law §3).

But for some there was still a mystery to be explained. The template or measure way of looking at the norm was not the best. More important were metaphors of chain and yoke. What made us do things? What yoked us to rules and legal norms? In Judaism we speak of the ‘yoke’ of the law. This seems a metaphysical question that for the Scandinavian legal realists remained unanswered (see Legal realism §1). Hence they answered it in a naturalistic way: by reducing the norm to our psychological feelings of constraint and being bound, which stemmed from an earlier, more magical age. Thus the magic was reduced to psychological states; the Freudian theory of normativity, as it were.

Norris, John (1657-1711)

John Norris was a philosopher in the Platonic tradition of the seventeenth century. His philosophy combines elements from both the French and English aspects of that tradition: he was an admirer of Henry More and was the leading English disciple of Malebranche, whose philosophy he did much to popularize in England. A churchman by profession, much of his writing is concerned with the practical application of divinity. Central to Norris' thought is his theory that the proper and immediate object of both human knowledge and human love is God, who is identified with truth. Thus necessary truths are known directly in God and, conversely, to know eternal and necessary truth is to know God.

John Norris was born at Collingbourne Kingston in Wiltshire, England. He was educated at Winchester College and Exeter College, Oxford, becoming fellow of All Souls College in 1680. In 1689, he was appointed rector of Newton St Loe. In 1692, through the good offices of Lady Masham and John Locke, he was appointed vicar of Bemerton near Salisbury, where he remained for the rest of his life. Norris' high regard for the Cambridge Platonists is evident from his brief correspondence with Henry More, published as *Letters Philosophical and Moral* and appended to his 1688 *The Theory and Regulation of Love* (see Cambridge Platonism). It is likely that Norris' early Platonist leanings combined with Augustinian strands in his theology to predispose him towards the philosophy of Malebranche. Norris himself denied that his discovery of Malebranche changed his philosophical standpoint (Acworth 1979: 64). None the less the impact of Malebranche is both clearly evident and duly acknowledged in his mature writings. But there were important aspects of Malebranche's philosophy which Norris did not accept, notably Malebranche's account of the distribution of Grace. Nor did he change his view that God acts out of pure benevolence in dealing with created things. It is perhaps truer to say, therefore, that Norris' reading of Malebranche enabled him to articulate his own analogous views more fully and more precisely.

His early writings (later published in *Miscellanies* in 1687) anticipate some of the main themes of his later, Malebranchian phase. For example, his essay 'Of the Advantages of Thinking' argues that ideas and necessary and eternal truths are in God, and are immediately present to the human mind as the proper object of human knowledge. Norris' concern in this essay is with proving the existence of God rather than with epistemology. The arguments are more fully stated in *Reason and Religion* (1689), which propounds Malebranche's theory of the 'vision in God', and are most fully developed in *An Essay towards the Theory of the Ideal or Intelligible World* (1701-4), which he had originally conceived while at Oxford as a *Metaphysica Platonica*. In this, his most substantial book, Norris argues for the existence of an ideal world of intelligible and unchanging entities which serve as the archetypes of the natural world. This ideal world exists in God as the 'omniform Essence' of God. Only the ideal world can be truly known. Since the mind cannot know matter directly, we have no certain knowledge of the physical world. Our knowledge of physical nature derives not from perception of physical bodies, but from our seeing the essences of things in God. It is this Malebranchean idealism which underlies Norris' critique of Locke in his *Cursory Reflections upon a Book Called an Essay Concerning Human Understanding* (1690), where he criticizes Locke for deriving the idea of God from sense knowledge.

Just as God is the proper object of human knowledge, according to Norris, so also, is God the proper object of human love. In *The Theory and Regulation of Love* (1688) Norris distinguishes two kinds of love: love of God and love of things. The former he calls love of concupiscence or desire, that is 'a motion of the Soul towards good'. The latter he calls love of benevolence, or disinterested love. The former is irresistible, uniting the soul with the good, which it lacks, that is, with God. Love of benevolence includes self-love and charity, and is the love most perfectly exemplified by God. Later, in his *Discourse concerning the Measure of Divine Love* (1693) he introduced an important modification to his account of human love of God, invoking Malebranche's occasionalist account of sensation. The proper object of desire is that which causes us pleasure, including pleasurable sensations. Since sensations are sense impressions planted in the mind by God on the occasion of the presence of corporeal objects, God is the cause of our pleasure. Therefore, as the true cause of our pleasure, God is the proper object of the love of concupiscence.

Norris' importance as a philosopher derives from his continuing the Platonic tradition of seventeenth-century English philosophy into the eighteenth century, and his popularizing the philosophy of Malebranche in England.

He also played a role as a mediator of philosophy to a growing lay readership through his books and his association with the journal *The Athenian Mercury*. By writing accessibly on philosophical themes, Norris was probably more influential than can be specifically documented, though particular mention might be made of John Wesley and Arthur Collier. He is also notable for the encouragement he gave to women interested in philosophy, among them Mary Chudleigh, Catharine Cockburn and Mary Astell.

Nous

Commonly translated as 'mind' or 'intellect', the Greek word nous *is a key term in the philosophies of Plato, Aristotle and Plotinus. What gives* nous *its special significance there is not primarily its dictionary meaning - other nouns in Greek can also signify the mind - but the value attributed to its activity and to the metaphysical status of things that are 'noetic' (intelligible and incorporeal) as distinct from being perceptible and corporeal. In Plato's later dialogues, and more systematically in Aristotle and Plotinus,* nous *is not only the highest activity of the human soul but also the divine and transcendent principle of cosmic order.*

In its pre-philosophical usage *nous* is only one among a number of terms for mind. It is chiefly distinguished from these other words by its tendency to signify 'intelligent' activity - realizing, understanding, planning, visualizing - rather than mental processes more generally, including the emotions.

The earliest Greek philosophers traded on this usage of the term. Heraclitus complained that 'much learning does not teach *nous*'. In Parmenides, the cognate verb *noein* and other related words (*noēma*, 'thought' and *noētos*, 'thinkable') are crucial to his argument. Drawing an absolute distinction between 'opinion' (*doxa*) based upon sense perception and 'truth' (*alētheia*), Parmenides argues that 'noetic' activity, properly speaking, is indissolubly linked to true discourse, valid reasoning and the cognition of reality. What is not true cannot be spoken or 'thought', a rule that applies not only to 'nothing' but also to the illusory data of sense perception. The reality that Parmenides' *nous* deduces and apprehends is unqualified 'being', homogeneous and invariant in time and place.

Anaxagoras (§4), with a cosmology strongly influenced by Parmenides, adopted *nous* as the controlling principle of the universe. Making *nous* quite separate from everything else, he characterized it as 'the finest and purest of all things, which has all knowledge about everything and the greatest power'. *Nous* causes the primordial mixture of other things to rotate and separate into distinct beings.

In the dialogues of Plato the treatment of *nous* was powerfully influenced by these antecedent conceptions. In his *Phaedo*, Socrates favours the idea that *nous* has organized the universe in the best possible way (an idea, he suggests, that Anaxagoras failed to carry through). This conception of *nous* was fully developed in other Platonic dialogues including the *Timaeus*, where it is figuratively expressed in the teleological thinking of the world's divine manufacturer (demiurge). In the *Republic*, the three great images of sun, divided line and cave are ways of distinguishing levels of reality and modes of cognition. Common to all three images is a distinction between the visible world of 'unknowable' phenomena and the 'noetic' world of stable and intelligible Forms. *Noēsis* - the highest activity of the soul's rational component - has cognition of the Forms as its objective, which it pursues by seeking understanding that is unhypothetical and absolutely secure. In ethical and psychological contexts Plato also uses *nous* as a term for the soul's 'rational component', with meanings that may be as broad as 'mind' in everyday English.

Although Plato's special uses of *nous* left their mark on Aristotle, the latter arrived at systematic ideas concerning *nous* as the distinctive faculty of the human soul (see Aristotle §19). In Aristotle's general model of the soul, psychic functions are realizations of bodily potentialities. *Nous*, by contrast, 'has no actual existence before it thinks', and it has no corresponding organ as 'perception' has in being the function of eye, ear, and so on. Like Plato, Aristotle links *nous* to the thinking of incorporeal 'forms' - the definable essences of things; but in contrast to Plato's independently existing 'Forms', those of Aristotle only become actual 'thought objects' in being thought since *nous* is identical in its actuality to what it thinks. For Aristotle, in contrast again with Plato, *nous* can only perform its activity with the help of data provided by 'imagination' (*phantasia*), which is the soul's capacity to represent sensory information, and it functions as the agent not only of theoretical activity but also of purposive action in everyday life.

In a notoriously obscure chapter (III 5) of his work *On the Soul*, Aristotle distinguishes *nous* as 'a capacity to become everything' from *nous* as 'a capacity to make everything', in the way that light makes potential colours actual. This 'active' *nous*, called 'immortal', has often been identified with the Aristotelian Unmoved Mover, whose life is 'a thinking of thinking' (see Aristotle §16). But Aristotle probably regarded human thought as being godlike rather than as being a product of the Unmoved Mover, who exists as an eternally transcendent thinker.

For Plotinus (§4), *nous* comprises 'primary reality', the domain of intelligence and intelligible beings. He construes this domain as an 'emanation' from the ineffable One, the ultimate principle of everything. Taken universally, *nous* corresponds more or less to a syncretism of Plato's Forms with Aristotle's Unmoved Mover. Everlastingly contemplating the One, *nous* is construed as an equivalence between thought thinking itself and intelligible beings as the only true thinkables. The activity of *nous* 'overflows' into 'soul', the principle of embodied life. As a lower level of reality, soul can only think things by treating them successively and separately. Human beings live primarily at the level of 'soul', but they also, by virtue of their immortal and 'undescended' self, have access to identification with *nous* and thereby to a mode of being in which thinker and thought are completely unified. In this transcendent condition, the mind is reality itself.

Stoics and Epicureans tend to use other words for the mind, probably because as rigorous physicalists they found *nous* too strongly tinged by Platonic metaphysics.

Nozick, Robert (1938-)

Although Robert Nozick has published on an enormous range of topics, he is best known as a political philosopher, and especially for his powerful and entertaining statement of libertarianism. In Anarchy, State, and Utopia (1974), Nozick presents an image of a fully voluntary society, in which people cooperate only on terms which violate no one's rights.

Nozick's other major contributions to philosophy include an analysis of knowledge, and an accompanying response to scepticism, an account of personal identity and contributions to decision theory and the theory of rationality.

1 Introduction

Robert Nozick was born in Brooklyn and studied at Columbia and Princeton Universities. He has taught at Harvard since 1969, and was appointed Arthur Kingsley Porter Professor of Philosophy in 1985.

Although he first came to prominence with two papers published in 1969, 'Newcomb's Problem and Two Principles of Choice' and 'Coercion', Nozick's first book (his defence of libertarianism), *Anarchy, State, and Utopia* (1974), is considered his most important work to date. This was followed by *Philosophical Explanations* (1981), The Examined Life (1989) (in which he remarks that he no longer considers himself to be a libertarian) and *The Nature of Rationality* (1993).

Nozick's eclecticism is accompanied by a particularly engaging writing style. He regrets the increasingly technical turn taken by recent intellectual work and has done much to make his own research accessible to a general readership without compromising its philosophical content. His openness appears in another way also: Nozick is often the first to point out the difficulties with his own position, believing that 'there is room for words on subjects other than last words' (1974: xii). Yet, in his search to break new ground he has rarely returned to a subject to answer critics or to fill in the gaps he admits are exposed.

2 *Anarchy, State, and Utopia*

Anarchy, State, and Utopia begins with the words: 'Individuals have rights, and there are things no person or group may do to them (without violating their rights)' (1974: ix). His conclusions fall into three parts: a defence of the minimal state; a theory of economic justice; and a utopian vision of society.

Nozick claims - in opposition to the anarchist - that the existence of a minimal state (the 'night-watchman' state of classical liberalism) is consistent with individual (negative) natural rights to life, liberty and property. To defend this claim he uses an 'invisible hand' argument to show how the state could emerge.

In Locke's state of nature (see Locke, J. §10), individuals have a natural right of self-defence and a right to punish those who violate their rights. Nozick argues that such people would rationally band together in groups to enforce their claims of justice. Commercial protection agencies would follow and, Nozick argues, such agencies would merge or join federations until a single 'dominant protection agency' exists. This yields what Nozick terms an ultra-minimal state, for not all individuals need join. However, Nozick believes that the dominant protection agency has the right to prohibit individuals from exercising their natural right to punish, provided it compensates them for this by offering protection services. Thus, ultimately the protection agency would satisfy two conditions Nozick believes sufficient to constitute a state: it (virtually) monopolizes legitimate coercion within its territory, and it offers protection to almost all. By showing that a minimal state could come into existence without violating rights, Nozick believes he has demonstrated that *at least* a minimal state is justified.

The centrepiece of Nozick's libertarianism, however, is his theory of distributive justice. Nozick argues that the more-than-minimal state - a welfare state, for example - would violate people's rights. Nozick's own theory of justice - the entitlement theory - falls into three parts: principles of justice in the initial acquisition of property; in transfer; and in rectification, which simply concerns how to rectify violations of the first two principles (see Justice §5; Property §3). The principle of justice in acquisition is not fully stated, although Nozick remarks that it must include one element taken from Locke: an individual's appropriation must not worsen any third party's condition. Nozick instead gives most attention to the principle of justice in transfer, which essentially states that a transfer is

just if, and only if, it is voluntary. His contention is that only his theory properly respects liberty. All others, he claims, are defeated by his notorious ‘Wilt Chamberlain’ example.

In this example, Nozick claims that any ‘pattern’ of holdings - each according to their needs, for example - will inevitably be destroyed by the free and voluntary trading and gift-giving behaviour of individuals. The only way of enforcing a pattern involves ‘constantly interfering’ in individuals’ lives: either by prohibiting certain transfers or by intrusively redistributing property. Even a system of taxation and welfare payments is rejected by Nozick on the grounds that it forces some people to labour for the benefit of others, without choice or reward. Accordingly, taxation is ‘on a par with forced labour’. Hence, any state more extensive than the minimal state will violate individual rights to liberty: ‘The socialist society would have to forbid capitalist acts between consenting adults’ (1974: 163).

The third part of Nozick’s project is to show that the minimal state is ‘inspiring as well as right’. Here he makes it clear that libertarianism is intended to provide a set of background rights and duties for society, but people may enter into whatever voluntary arrangements they wish. Thus Nozick argues that a group may set up any type of community they wish, provided they have the resources and do not coerce others to join them. Thus libertarianism is viewed as a ‘framework for utopia’ in which individuals can act out their own model of utopia, in company with like-minded others (see Libertarianism §§1, 3).

Nozick’s views have generated an enormous critical literature. Critics claim that the entire weight of his position stands on the justification of the initial acquisition of individual property rights. And on this point Nozick is particularly weak, doing so little to state and defend his principle of justice in acquisition. Critics have also doubted that Nozick can justify even the minimal state, given the very strong assumptions of individual freedom with which he starts. Nozick has not published a response to these criticisms.

3 *Philosophical Explanations*

Nozick’s second book, *Philosophical Explanations*, ranges unconfined over topics in metaphysics, epistemology and the philosophy of value. While here he makes important contributions to the issues of personal identity and the foundations of ethics, his treatments of knowledge and scepticism have attracted the greatest attention.

What is it to know something, as distinct, for example, from guessing correctly? The traditional analysis of knowledge asserts that knowledge is justified true belief. Yet this seems to have been refuted by ‘Gettier examples’: once we appreciate that some beliefs, while justified, are nevertheless false, it is a short step to realize that a justified belief might be true by accident or fluke (see Gettier problems).

To avoid such problems Nozick presents the ‘truth-tracking’ theory. This is an externalist theory, and Nozick’s own approach is a variety of reliabilism (see Reliabilism), in which, broadly, one has knowledge if one’s true beliefs are generated by a reliable mechanism. Nozick claims that, if ‘*S* knows that *p*’, then four conditions are individually necessary and jointly sufficient:

(1) *p* is true.
(2) *S* believes that *p*.
(3) If *p* were not true then *S* would not believe it.
(4) If *p* were true then *S* would believe it.

Conditional statements (3) and (4) replace the appeal to justification in the traditional account. These are to be interpreted as subjunctive or counterfactual conditionals rather than as material implications. Using possible worlds semantics for counterfactual conditionals (see Counterfactual conditionals §3), the third condition can be read as: ‘In close possible worlds where *p* is not true, *S* does not believe *p*’. If your belief is true by accident, there will be a close possible world in which you still have that belief, even though it is false. The belief fails therefore to meet the third condition, and so does not count as knowledge.

We can now see why Nozick calls his theory the ‘truth-tracking’ theory: knowledge requires not just that you believe the truth, but that your belief ‘tracks’ the truth among close possible worlds. Together the third and fourth conditions require that, not only do you believe the truth, but in reasonably similar situations where it is false you would not believe it, and where it is true you would.

Nozick's analysis gives him a reply to the sceptic about knowledge. If we grant that you cannot know that you are not now a brain in a vat on Alpha Centauri, then it seems to follow that you cannot know anything else: for example, that you are now on Earth, reading. Nozick's reply is to point out that the sceptic's argument presupposes that 'knowledge is closed under known logical implication', and that his own analysis of knowledge shows that this assumption is false.

The closure principle is a relatively simple idea. If you know that *p*, and that *p* logically entails *q*, then according to the closure principle it follows that you know that *q*. The sceptic uses this principle (in reverse) to argue that we have no knowledge. If I am reading on Earth, then it logically follows (and I know that it follows) that I am not a brain in a vat on Alpha Centauri. Hence, according to the closure principle, if I know that I am reading on Earth, then I know that I am not a brain in a vat. But, the sceptic claims, as I do not know that, I do not know that I am reading on Earth. Indeed, I cannot know anything known to be inconsistent with my being a brain in a vat on Alpha Centauri.

The closure principle is central to the sceptic's case. But on Nozick's analysis the principle is false. Nozick points out that whether or not an individual knows a proposition depends on how their beliefs vary over a set of close possible worlds. But the possible worlds to take into account differ according to the proposition under consideration. Hence, I can know that *p*, and know that *p* entails that *q* without knowing that *q*, and the sceptic's argument falls.

While an ingenious response, critics argue that Nozick's analysis of knowledge should be rejected. For it has the peculiar consequence that I can know a conjunction '*p* and *q*' without knowing one of the conjuncts *q* for the set of possible worlds in which '*p* and *q*' is true is not identical to the set of possible worlds in which '*q*' is true. Although this is a consequence Nozick points out himself, for many it is a *reductio ad absurdum* of his approach.

4 *The Examined Life* and *The Nature of Rationality*

The Examined Life, Nozick's third book - a book about 'living and what is important in life' (1989: 11) - has not made much impact on the philosophical world. However, his fourth, *The Nature of Rationality* (1993), marks a return to issues of decision theory and rationality, and so contributes to ongoing debates within the analytic tradition.

Nozick was the first to present Newcomb's problem to the philosophical world, and his discussion has remained a classic work in decision theory, emphasizing the distinction between evidential and causal decision theory. In *The Nature of Rationality* he introduces a new idea: symbolic utility. An action or decision may be symbolic - expressive of an emotion or attitude, for example - and so may have value not so much in its effects, but by its standing as a symbol. To illustrate, Nozick points out that for some people minimum wage legislation may have value as a way of symbolizing the idea of helping the poor, even if it turns out to be ineffective as a policy. Acting rationally, on Nozick's view, is a matter of 'maximizing decision-value', which is a weighted sum of causal, evidential and symbolic utility (see Decision and game theory).

Numbers

Numbers are, in general, mathematical entities whose function is to express the size, order or magnitude of something or other. Historically, starting from the most basic kind of number, the positive integers (1, 2, 3,...), which appear in the earliest written records, the notion of number has been generalized and extended in several different directions - often in the face of considerable opposition.

Other than the positive integers, the most venerable are the rational numbers (fractions), which were known to the Egyptians and Mesopotamians. The discovery, by Pythagorean mathematicians, that there are lengths that cannot be expressed as fractions occasioned the introduction of irrational numbers, such as the square root of 2, though the Greeks managed only a geometric understanding of these. The number zero was recognized, first in Indian mathematics, by the seventh century; the use of negative numbers evolved after this time; and complex numbers, such as the square root of -1*, appeared first at the end of the Middle Ages. Infinitesimal numbers were developed by the founders of the calculus, Newton and Leibniz, in the seventeenth century (and were later to disappear from mathematics - for a time); and infinite numbers (ordinals and cardinals) were introduced by the founder of modern set theory, Cantor, in the nineteenth century.*

The introductions of three of these kinds of number, in particular, occasioned crises in the foundations of mathematics. The first (concerning irrational numbers) was finally resolved in the nineteenth century by the work of Cauchy and Weierstrass. The second (concerning infinitesimals) was also resolved then, by the work of Weierstrass and Dedekind. The third (concerning infinite numbers), which involves paradoxes such as Russell's, still awaits a convincing solution.

It is seemingly impossible to give a rigorous definition of what it is to be a number. The closest one can get is a family-resemblance notion, with very ill-defined boundaries.

1 Natural numbers

All human societies would appear to have some form of counting, however limited, both for size - cardinality (one, two, three,…) - and for order - ordinality (first, second, third,…). The recognition that an infinitude of positive integers could be used for these purposes was already in place in the earliest civilization from which we have written records, that of Egypt *circa* the fourth millennium BC. The investigation of basic arithmetic operations (addition, multiplication and so on) was also well under way then. This was continued in the next great Middle Eastern civilization, that of Mesopotamia (Babylon), *circa* the second millennium BC. The investigations were greatly facilitated by the Mesopotamian invention of place-notation, that is, the idea that a single numeral can represent different quantities depending on where it occurs in a string of numerals. Thus, for example, in decimal notation, the first '2' of '2,121' represents two thousands and the second represents two tens. (The Mesopotamians actually preferred a sexagesimal to a decimal base.)

The *natural* numbers comprise the positive integers together with zero. The idea of zero as a number was not to be found in either of these civilizations, although the Mesopotamians did sometimes leave a gap where we would now write a zero. (Thus ' 2 2' might represent 202 or 2,020, and so on.) Though the origin of the idea is uncertain, zero was certainly being used by the seventh century AD by Indian mathematicians, who had also developed place-notation and used a decimal base. They therefore possessed, in effect, our modern number system (though the symbols they used were different). This system was taken up in the Arabian civilization around the eighth century, and thence passed into Europe around the twelfth.

2 Rational and irrational numbers

Positive integers quantify wholes. Once one starts to measure, it becomes clear that a way is required to quantify parts. *Rational* numbers, as ratios of natural numbers (with non-zero denominator), clearly serve this function. These were known to the Egyptians, at least in the form of unit fractions (of the form $1/n$) and, in a more sophisticated and general form, to the Mesopotamians. Decimal fractions (of the form 0.23) appear to have been developed by Arabic mathematicians, and by the time we reach Stevin in late sixteenth-century Europe, the modern computational system for rational numbers is essentially in place.

The creation of modern mathematics is usually reckoned to have occurred in Ancient Greece in the second half of the first millennium BC. What was distinctive about the Greek approach was that mathematics was freed from its practical roots and took on a purely theoretical form. In particular, the central concern of Greek mathematics was proof, especially proofs in geometry. As far as arithmetic goes, the first part of this epoch was dominated by Pythagoreanism, according to which everything can be explained in terms of the positive integers. (It follows that rational numbers are of little theoretical importance: given two lengths to compare, if one chooses one's unit of measurement small enough, the lengths will be integral.)

The discovery that the Pythagorean assumption was wrong came as a distinct shock. Most simply, the diagonal of a unit square (whose length is the square root of two) is not commensurable with its sides. The proof of this (one of the first *reductio* arguments in the history of mathematics) is now celebrated. It is not known who discovered it, though it was probably one of the later Pythagoreans, *c*.400 BC. At any rate, it inaugurated the first of three crises in the foundations of mathematics that have been associated with the introduction of a new kind of number.

The new numbers in this case are *irrational* numbers (that is, numbers which cannot be written as a ratio of integers - written as decimals they are infinite and non-repeating), such as the square root of two (and pi (π), although the irrationality of this was not proved until the eighteenth century by Lambert). They are required, together with rational numbers, for general quantification of length: in fact, the only conception of such magnitudes available to the Greeks was as geometric lengths. Given this representation, some geometric account of arithmetic operations had to be given. The hardest of these is division, which was solved by Eudoxus (*c*.360 BC) in his theory of proportions, given in book 5 of Euclid's *Elements*. But even for Eudoxus, ratios were not entities in their own right. Operations which treat irrational numbers in the form of surds (expressed in ways such as $\sqrt{2}$, $\sqrt[3]{71}$), as bona fide entities, can be found in Indian mathematics and, in particular, in the seventh-century mathematician Brahmagupta. Some use of surds was made by Arabic mathematicians, but their use did not become common until the sixteenth century (for example, in the work of Stevin and Cardan). A clear statement to the effect that irrational numbers are first-class numerical citizens can be found in Newton, in the seventeenth century; however, an adequate understanding of what this citizenship amounted to had to wait until the nineteenth century.

3 Negative and complex numbers

Subtraction had been familiar to mathematicians since the earliest times. The idea that a sensible quantity might itself be negative, however - and what the sense of it might be - took a long time to catch on. *Negative* numbers, the rules for operating with them, and their use as roots of equations appear in Brahmagupta, and were consequently known to Arabic mathematicians - though they did not use them as roots of equations. The first time they appear in this way in European mathematics is in the work of fifteenth-century mathematician Nicholas of Chuquet (who, however, did not allow zero to be a root!). Even Cardan, a century later, who employed negative roots extensively, called them 'fictional'. The idea that negative numbers might correspond to direction reversal is to be found in the early seventeenth-century mathematician, Girard; but, even after the invention of analytic geometry by Descartes a little later, many mathematicians simply ignored the negative parts of the plane. And even as late as the middle of the eighteenth century some textbook writers were still disputing the claim that the product of a pair of negative numbers is positive.

Once the use of negative numbers became common mathematical practice, the thought that there might be a new kind of number to provide for their square roots was not far behind. If we call all of the numbers mentioned so far *real* numbers, and write the square root of -1 as i (following Euler), the product of i with any real number is called an *imaginary* number. More generally, the sum of a real number and an imaginary number ($a + \mathrm{i}b$) is called a *complex* number. One of the earliest occurrences of complex numbers in mathematics is in the work of Cardan, who observed, as we would now put it, that a cubic equation with a real root may also have complex roots, though Cardan himself regarded this observation as useless. A few years later, Bombelli articulated the use of complex numbers (in the same context) much further. Opposition to them did not then cease, however; for example, their use was frowned upon by Newton. But by the time of, and especially in the work of, Euler, in the eighteenth century, complex numbers had been shown to have numerous uses, both as the solutions of equations and elsewhere - for example, in important relationships between trigonometric functions. And by the time that Gauss, in the early nineteenth century, showed that every polynomial equation with complex coefficients has complex roots, complex numbers were well entrenched. With the development of electromagnetic theory later in the

century, complex numbers were shown to be capable of representing even physical quantities (for example, impedance).

The problem of what sense to make of complex numbers was also solved by Gauss and later contemporaries, such as Argand. The complex number $x + \mathrm{i}y$ could be thought of as the point (x, y) in two-dimensional Euclidean space (now usually called the Argand plane), with the arithmetic operations on complex numbers defined in a suitable way. This prompted the idea that points in a higher-dimensional space could also be thought of as numbers of a certain kind. Defining a suitable notion of multiplication for points in a three-dimensional space turned out to be impossible, but the problem was solved for four dimensions by the Irish mathematician William Hamilton later in the nineteenth century. Hamilton defined a class of numbers known as 'quaternions', of the form $x + \mathrm{i}y + \mathrm{j}z + \mathrm{k}w$, where $\mathrm{ijk} = \mathrm{i}^2 = \mathrm{j}^2 = \mathrm{k}^2 = -1$. The properties of quaternions were investigated for some years, but no real use was found for them, so the investigations lapsed. By this time, the observation that a somewhat different set of operations on points in Euclidean space might be fruitful had been made, and vector algebra was born. (If one thinks of complex numbers as two-dimensional vectors, then complex addition and vector addition are the same thing, but complex multiplication and the various vector multiplications are distinct.)

4 Infinitesimal numbers

The numbers discussed so far have all been finite. But numbers of some kinds are infinite - or their intuitive inverse; infinitesimal. It is sometimes (dubiously) claimed that infinitesimals can be found in Greek mathematics. What certainly can be found, from about the third century BC on, is a method called 'the method of exhaustion', (probably) invented by Eudoxus and developed by Archimedes. The main purpose of this method is the computation of areas and volumes of non-rectilinear geometric figures, and requires their approximation by rectilinear figures. For example, a circle is approximated by a regular polygon inscribed within it. As the length of the sides of the polygon decreases (and the number of sides increases) the approximation gets closer. By the late sixteenth century we find mathematicians such as Stevin and Wallis suggesting, in effect, that if we make the sides of the polygon infinitesimally small, the approximation will be exact - or, at least, will differ only infinitesimally from the true value. Hence, a new kind of number, *infinitesimals*, had to be recognized, to quantify infinitesimal lengths.

The use of infinitesimals in essentially this way was developed by Newton and Leibniz in the next century as the foundation of modern calculus (see Analysis, philosophical issues in §1). Though their inventions were independent, and used quite different notations, the essential ideas were the same. For example, to determine the gradient of the curve $y = x^2$ at the point $x = a$, we consider a point on the curve an infinitesimal distance *d* away along the *x*-axis. The slope of the line joining these two points is

$$\frac{(a+d)^2 - a^2}{d} = \frac{2ad + d^2}{d}$$
$$= 2a + d$$

but since *d* is infinitesimally small, we can disregard it. Hence the gradient is 2*a*.

The power of infinitesimal methods was so great, in both pure and applied mathematics, that they soon became entrenched. However, many people - most notably Berkeley - were severely critical. In particular, infinitesimals had at the same time to be both non-zero (since one divided by them) and zero (since one ignored them). This dilemma inaugurated the second foundational crisis in mathematics associated with the introduction of a new kind of number. But this one would have to wait only 200 years for a solution.

5 Transfinite numbers

It is clear that there are infinite quantities in mathematics, and hence that there must be a size that these quantities can be, namely, infinite. But for most of the history of mathematics, infinitude was thought of as mathematically indeterminate, and hence there was little to be said about the quantity 'infinity'. (One does, however, sometimes find mathematicians - even of the stature of Euler - taking it as a definite quantity, in particular, as the reciprocal of zero.) Even in the heyday of the infinitesimal calculus, infinite numbers played little part (though Leibniz certainly held that the reciprocals of distinct infinitesimals were distinct infinite numbers). The recognition of different orders of infinity, and consequently of the sense of infinite numbers, therefore came as another highly contentious

idea.

This recognition is almost entirely due to Georg Cantor in the late nineteenth century. He realized that, given some iterable operation (for example, forming the set of topological limit points of some set of points), it made sense to consider the result of having applied the operation an infinite number of times, and then to apply the operation again, and again…indefinitely (see Cantor, G. §1). To quantify this ordering, Cantor introduced a new class of infinite numbers, *transfinite ordinals*, the least of which he denoted by a lower-case omega, ω (see Set theory §2). He also defined arithmetic operations on these numbers which generalize the operations on finite numbers, but which have rather unusual properties. For example, addition is not commutative: $\omega + 1 \neq 1 + \omega$.

Having generalized the notion of order into the infinite, Cantor next generalized the notion of size. To do this he needed a criterion of size that would work (even) in infinite domains. He adopted the criterion (also suggested by Frege (§8)) that two collections have the same size just if their members can be put into one-to-one correspondence (that is, each member of either collection corresponds to exactly one member of the other). He observed that adding members to an infinite set may not increase its size. (This fact had been noted by some previous mathematicians - for example, Galileo - who thought it so absurd that they rejected infinity as a quantity.) In another of the most famous *reductio* arguments in the history of mathematics, Cantor also established that for any infinite collection, there is one of greater size. This is now called 'Cantor's theorem' (see Cantor's theorem). To quantify the different sizes Cantor introduced a new kind of infinite number, *transfinite cardinals* (see Set theory §3), denoted by the Hebrew letter aleph ($\aleph$) with a subscript ($\aleph_0$ being the smallest, the size of the natural numbers); and defined arithmetic operations on these which, again, generalize the finite case. These operations also have striking properties: for example, double any aleph and you get what you started with.

It should be noted that natural numbers can be thought of indifferently as ordinals or cardinals. This is because, canonically, we count the size of a finite collection by ordering, and its cardinality is n just if the last object in the ordering is the nth. However, transfinite ordinals and cardinals are quite distinct since, as just observed, if one adds further objects to an ordered set, the size may remain the same. Transfinite ordinal and cardinal arithmetics are also quite distinct. Cardinal addition, for example, is commutative, where ordinal addition is not. It is worth noting that there are very simple questions concerning basic transfinite arithmetic operations that are still unanswered (see Continuum hypothesis).

Cantor's introduction of transfinite numbers into mathematics did not entail the use of infinitesimals. This is because the unusual properties of (cardinal and ordinal) multiplication allow no obvious sense to be given to the notion of division, and so not to reciprocation. However, the use of infinite numbers brought its own problems. In particular, the totality of all ordinal numbers is an ordered collection and hence must have an ordinal, which must be greater than, and so distinct from, all ordinals. Similarly, the totality of all objects must have the largest possible cardinal, but, by Cantor's theorem, there is a larger. These paradoxes are now called the Burali-Forti paradox and Cantor's paradox, respectively; Russell's paradox, concerning the set of all sets that are not members of themselves, is a stripped-down version of Cantor's (see Paradoxes of set and property §4). They heralded the third crisis in the foundations of mathematics associated with the introduction of a new kind of number; a crisis which, unlike the first two, is as yet not satisfactorily resolved. These paradoxes fuelled the rejection of Cantor's ideas by some, including Kroneker; but despite this, they were absorbed into orthodox mathematics within about fifty years.

6 Weierstrass and Dedekind

The final resolution of the first two crises we met (concerning irrationals and infinitesimals) took place in the nineteenth century, a period when mathematicians became particularly concerned with the rigorous foundations of their subject. In this context, the work of Weierstrass and Dedekind is particularly significant.

Early in the nineteenth century, the notion of a 'limit' appeared in Cauchy's formulation of the calculus. His method differed from that set out in §4 above as follows: instead of taking d to be some infinitesimal quantity, we let it be a finite quantity, and then consider the limit of what happens when d approaches zero (the limit being a quantity that may be approached as close as we please, though never, perhaps, attained). Despite the fact that Cauchy possessed the notion of a limit, he mixed both infinitesimal and limit terminology, and it was left to Weierstrass, later in the century, to replace all appeals to infinitesimals by appeals to limits. At this point infinitesimal numbers disappeared from mathematics (though they would return, as we shall see).

Weierstrass also gave the first modern account of negative numbers, defining them as signed reals, that is, pairs whose first members are reals and whose second members are 'sign bits' ('$+$' or '$-$'), subject to suitable operations.

A contemporary of Weierstrass, Tannery, gave the first modern account of rational numbers. An 'equivalence relation' is a relation *R* that is reflexive (*xRx*), symmetric (if *xRy* then *yRx*) and transitive (if *xRy* and *yRz* then *xRz*). Given an equivalence relation on a domain of objects, an 'equivalence class' is the set of all those things in the domain related to some fixed object. Tannery defined the rationals as equivalence classes of pairs of natural numbers (the second of which is non-zero), under the equivalence relation '$\sim$' (tilde), defined as follows.

$\langle m, n\rangle \sim \langle r, s\rangle$ iff $m.s = r.n$

The problem of irrational numbers was finally solved independently by Weierstrass, Cantor and Dedekind, who gave different but equivalent constructions of real numbers. Weierstrass' is in terms of infinite decimal expansions; Cantor's is in terms of convergent infinite sequences of rationals. Dedekind's construction is the simplest: consider any splitting of the rational numbers (which can be taken to include the integers, since the integer *n* may be identified with the rational number $n/1$) into two non-empty disjoint collections *L* ('left') and *R* ('right'), such that anything less than a member of *L* is in *L*, and anything greater than a member of *R* is in *R*. This pair is now called a 'Dedekind cut' (or 'section'). Real numbers (including irrational numbers) can be thought of as such sections (or just one of their parts).

Dedekind also gave the first axiom system for the natural numbers, in terms of an initial number and the successor operation ($+1$). In modern form, the axioms are as follows:

(1) 0 is a number.
(2) The successor of any number is a number.
(3) 0 is the successor of no number.
(4) Any two numbers with the same successor are the same.
(5) If 0 has some property, and the successor of any number with that property also has it, then all numbers have it.

These axioms, together with the recursive definitions for addition and multiplication (also given by Dedekind), are now usually named after Peano, who gave a formalized version a few years later.

7 Set-theoretic reduction

The drive for rigour in the foundations of number theory reached its height in the reduction of all numbers to sets, due to the logicists Frege, Russell and Whitehead at the turn of the twentieth century (see Logicism). The key to this was a set-theoretic definition of cardinal and ordinal numbers. The cardinal numbers were defined as equivalence classes of sets under the equivalence relation 'can be put into one-to-one correspondence with'. (For Russell and Whitehead, this was restricted to sets of fixed type, in an attempt to avoid the paradoxes of infinite number - see Theory of types.) A 'well-ordering' on a set is an ordering such that every non-empty subset has a least member in the ordering (see Set theory §2). Two well-ordered sets are 'order-isomorphic' if they can be put into a one-to-one correspondence that preserves the ordering. The ordinal numbers were defined as the equivalence classes of well-ordered sets (of a given type) under the equivalence relation of order-isomorphism. Cardinal and ordinal arithmetic operations were defined in an appropriate fashion.

Given the ordinals, other numbers could then be defined in a relatively straightforward way. Natural numbers are the finite ordinals (which can be shown to satisfy the Peano axioms - see §6 above); rational numbers can be defined by the Tannery construction; real numbers as Dedekind sections; negative numbers as Weierstrassian pairs; complex numbers can be defined as pairs of signed reals, thought of as points on the Argand plane. In each case, arithmetic operations can be defined in natural ways.

Since the Frege/Russell reduction, several other non-equivalent, but equally good, definitions of the cardinal and ordinal numbers have been discovered (and in virtue of this, the claim that these numbers just *are* certain sets is difficult to maintain). The most elegant of these is due to von Neumann. According to this, each ordinal is simply the collection of all smaller ordinals. (Thus, zero is simply the empty set, the least infinite ordinal is the set of natural numbers, and so on.) Cardinal numbers are identified with 'initial' ordinals, that is, least ordinals of each

size.

8 Developments from logic

Work in mathematical logic in the twentieth century has provided several notable developments bearing on numbers. Three are particularly important. The first was the proof by Gödel in 1931 that the Peano axioms, and all other consistent axiom systems for arithmetic, are incomplete, in the sense that there are truths of arithmetic that cannot be proved from the axioms - at least if the underlying logic is first-order (see Gödel's theorems). The axioms are complete if the underlying logic is second-order and the induction principle (5) is formulated as a second-order axiom and not just a first-order schema; but second-order logic is not itself axiomatizable (see Second- and higher-order logics §1). This raises profound questions about the nature of both numbers and our knowledge thereof, that fall outside the bounds of this entry.

The second development concerns the paradoxes surrounding transfinite numbers. The orthodox view that has emerged this century is that embedded in Zermelo-Fraenkel set theory (ZF). According to this, there just is no totality of all ordinals, all sets or other 'large' collections, and so the question of their size does not arise. Although this account provides enough set theory for most mathematics (though not all: category theory appears to require large sets of just this kind), it can hardly be said to be conceptually adequate. For example, standard logic defines the sense of a quantifier in terms of the domain (totality) over which it ranges. It is therefore unclear what the sense of the quantifiers of ZF is, if, as it claims, there is no such totality. (See Priest 1987.)

The third development is due to Robinson and is called 'nonstandard analysis' (see Analysis, nonstandard). As was proved originally by Löwenheim and Skolem, (first-order) theories of number have nonstandard models (see Löwenheim-Skolem theorems and nonstandard models). In particular, any theory of the reals will have such models. Robinson showed that in all of these models, there are non-zero numbers that are smaller than any real number: infinitesimals. Using these, he demonstrated that the reasoning of the infinitesimal calculus (which is much more intuitive than limit reasoning) can be interpreted in a perfectly consistent manner. Hence, infinitesimals have been rehabilitated as perfectly good numbers.

9 Number in general

The preceding review of the development of the notion of number naturally prompts the question of what a number is. One might interpret this as the question of whether numbers are Platonic objects, mental constructions, or nothing more than mystified numerals. This is a central issue in the philosophy of mathematics.

Alternatively, in virtue of the plethora of kinds of numbers we have seen, one might interpret the question as asking what makes entities of certain kinds, but not others, numbers. Beyond the rather vague characterization with which this article began, it seems difficult to give a general characterization of number. The most fundamental numbers (both historically and conceptually), the natural numbers, measured size (or order), were subject to distinctive operations (such as addition) and could be the roots of equations. Each of these central features has played a role in generating new kinds of numbers (different concerns being dominant on different occasions). The result is a collection of entities which are related by family resemblance (as observed by Wittgenstein in §67 of *Philosophical Investigations*), though the boundaries of the family seem somewhat arbitrary. It is difficult to see why, for example, complex numbers (or quaternions) should be called numbers, but not vectors or numerical matrices; both of these share the central features of natural numbers.

This conclusion is reinforced by recent work by Conway (1976). He gives a (transfinite) recursive construction that generalizes both the Dedekind construction of the reals and the von Neumann construction of ordinals. Essentially, a number is any pair, $\langle L, R\rangle$, such that all the members of *L* and *R* are numbers, and every member of *R* is greater than or equal to ($\geq$) every member of *L* (see Analysis, philosophical issues in §2). ' $\geq$' and the arithmetic operations are also defined in a natural recursive manner. The construction generates virtually all the numbers we have met in this article, including infinitesimals, but excluding, notably, the complex numbers (and if cardinals are to be identified with initial ordinals, a non-uniform definition of arithmetic operations is necessary). Moreover, the construction generates many novel numbers, for example, notably, numbers obtained by applying the full range of real-number operations to infinite numbers, for example, $\omega - 1$, $\sqrt{\omega}$, which make no sense on the usual understanding. Moreover, a simple generalization of the construction (dropping the ordering condition on

L and *R*), produces even more number-like objects (which Conway calls ‘games’, because, in a certain sense, they code the strategic possibilities in a two-person game).

Just conceivably, a unifying account of number might eventually be found, but in the meantime the emergence of new kinds of numbers seems likely. For example, there are nonstandard inconsistent models of arithmetic which contain inconsistent numbers (natural numbers with inconsistent properties). These have some notable applications. For example, some of them can be shown to provide solutions for arbitrary sets of simultaneous linear equations. (See Mortensen 1995.) And just as the existence of nonstandard models of analysis made infinitesimals legitimate, so might these legitimize the notion of an inconsistent number.

Numenius (*fl. c.* mid 2nd century AD)

Numenius was a Platonist philosopher. He came from Apamea (Syria) and wrote in Greek. His work - now lost - is usually considered Neo-Pythagorean in tendency, and exercised a major influence on the emergence of Neoplatonism in the third century. A radical dualist, he postulated the twin principles of god - a transcendent and changeless intellect, equated with the Good of Plato's Republic - and matter, identified as the Pythagorean Indefinite Dyad: god is good, matter evil. In addition to this supreme god, he added at a secondary level a creator-god, one of whose aspects is the world-soul, itself further distinguished into a good and an evil world-soul. He had a strong interest in Oriental wisdom, especially Judaic, and famously called Plato 'Moses speaking Attic'.

1 Life, work and influence

Nothing is known of Numenius' life, but he can be dated with reasonable accuracy by the fact that he is attested as the teacher of one Harpocration, who was also influenced by the Athenian Platonist Atticus, who in turn flourished in the AD 170s. He is often mentioned in conjunction with a 'companion', Cronius, who was presumably associated with his school, and who may possibly be the addressee of Lucian's treatise on Peregrinus.

Of his works none has survived, but some extracts of his dialogue *On the Good* are preserved by Eusebius in his *Preparation for the Gospel*, as also are some considerable passages from a lively polemical work, *On the Apostasy ['Diastasis'] of the Academics from Plato*, which helps to clarify Numenius' own position, while providing some useful data on the New Academy. Alongside this, we know of the works *On the Indestructibility of the Soul* and *On the Secret Doctrines of Plato*, treatises *On Numbers* and *On Place*, and a work called *Epops*, or 'The Hoopoe', which probably embodies a pun on *epopteia* (mystical vision). We also have an extended account of his doctrine on matter preserved by the late Roman commentator on Plato's *Timaeus*, Calcidius, who may well be more extensively indebted to him than he acknowledges.

His philosophical importance is considerable. He was a major influence, through the mediation of Ammonius Saccas (not to be confused with Ammonius, son of Hermias), on the father of Neoplatonism Plotinus and his followers Amelius and Porphyry, as well as the Christian theologian Origen (see Neoplatonism §1; Porphyry §4; Origen). His Pythagoreanism consists of presenting Plato as a disciple of Pythagoras (see, for example, fragments 7, 24.57), although without derogating from Plato's greatness (as was done by more extreme Pythagoreans, such as Moderatus of Gades).

Numenius was much interested in the wisdom of the East and in comparative religion. He attracted the interest of Church Fathers by his references to Jahveh, Moses and even Jesus (fr. 1). Indeed, he described Plato as 'Moses speaking Attic' (fr. 8), which seems to imply an acceptance of something like Philo's wholesale allegorization of the Pentateuch (see Philo of Alexandria §1). There has been speculation that he was himself of Jewish stock - his hospitality to the Jewish tradition is certainly notable - but this is not a necessary inference. Numenius may simply be reflecting the syncretistic religious and philosophical milieu in which he lived.

2 Metaphysics

Numenius' views on ethics and logic are not known (although his ethical stance may be assumed to be austere), so we may confine ourselves to his metaphysics and psychology. He is at odds with previous Pythagoreans in maintaining a radical dualism between the first principles of god (the Monad, the Good) and matter (the Dyad), instead of subordinating the material Dyad to the all-generating Monad, as is done by his Pythagoreanizing predecessors from Eudorus through Moderatus to Nicomachus of Gerasa. Numenius' dualism allies him rather with Plutarch and Atticus, and leads him, like them, to postulate an evil world-soul, derived from a reading of Plato (*Laws* X) to balance the beneficent world-soul (see Plutarch of Chaeronea§§3-4).

Numenius proffered a system of three levels of spiritual reality: a primal god (the Good, or the Father), who is almost supra-intellectual; a secondary, creator-god (the demiurge of Plato's *Timaeus*); and a world-soul. In this he anticipates to some extent Plotinus, although he was more strongly dualist than Plotinus in his attitude to the physical world and matter, and does not take the radical step of declaring his first principle to be above intellect - although his intellect is an intellect *at rest*, as opposed to the secondary intellect, which is *in motion* (fr. 15). Numenius does seem to have felt the awkwardness of attributing both intellectual and creative activity to a first

principle which is utterly transcendent and completely unitary (in fragment 12, he is insistent that the first god is ‘inactive in respect of all activity’), but he was no more willing than his predecessors to declare it to be ‘beyond being *and* intellection’. Indeed, mindful of Plato (*Sophist* 248e) he is even unwilling to deny it a form of motion, speaking of the ‘rest’ (*stasis*) of the first god as ‘an innate motion’ - ancestor of the ’spiritual motion’ of intellect in later Neoplatonism.

The distinction between his second and third gods is rather subtle, and has led to confusion. In fragment 11 he declares that the second and third gods are ’one’, but a division results from the demiurgic activity of the second god with regard to matter. This difference splits the god into two aspects, similar to the ’transcendent’ and ’immanent’ aspects of the *logos* of god in the philosophies of Philo of Alexandria and Plutarch (at least in the latter’s treatise *On Isis and Osiris*). The ’lower’ aspect of the demiurgic intellect may be viewed as a ’third god’, and constitutes a rational world-soul, which bestows form on the chaos of matter to create the physical world at the price of suffering multiplicity itself.

Numenius is, like any later Platonist, concerned with basing his doctrine on suitable Platonic proof-texts. His doctrine of three gods he derives primarily from the Platonic *Second Letter*, which he would have naturally taken as genuine, but he derives confirmation also from a well-known passage of the *Timaeus*, where he takes the ‘essential living being’ (*auto ho esti zōon*) as the primal god (equated in turn with the ’Good’ of the *Republic*). This essential living being the demiurgic intellect contemplates, thus bringing into being the world of Forms, while also ‘discursively intelligizing’ (*dienoēthē*) the physical world, thus constituting itself, or a lower projection of itself, as the world-soul (fr. 22). The fact that the *Timaeus* myth presents the demiurge as creating the world-soul may have led Numenius to describe his third god as a ‘creation’ (*poiēma*), as Proclus alleges (fr. 21) it is certainly an active principle.

Adumbrated in this fragment is his doctrine of *proschrēsis* (‘calling in the help of… ’) which, although obscure, may anticipate Neoplatonic doctrines of the interaction between *hypostases* (see Plotinus §3). Each level of being (the primal god, the demiurge) performs its proper role only by *proschrēsis* of the level of being below it. This serves to link up the entire spiritual world into a dynamic whole. It may be behind the rather bombastic imagery of ’grandfather, son, and grandson’, which Proclus criticizes (fr. 21), and which Numenius seems to have used to characterize the relations between the three principles.

It is in his doctrine of matter (Calcidius, fr. 52) that Numenius’ dualism emerges most strongly. Matter, as the Pythagorean Indefinite Dyad, is coeval with the primal god, and is a positively evil force. Numenius is scornful of his predecessors’ attempts to derive the Dyad from the Monad by one formula or another (fr. 52.15-). He discerns the postulation of a maleficent, ‘material’ soul in Plato *Laws* (X 896e), which, like Plutarch before him, he sees as represented also by the ‘disorderly cause’ of the *Timaeus* (see Plutarch §§3-4). This can be brought to order by the demiurgic intellect, but never completely neutralized.

This ’evil’ soul is represented in each individual also (frs 43-4), although how exactly its functions are distinguished from those of the rational soul is less than clear. It is not a simple distinction between rational and irrational soul, since Numenius also envisages the rational soul as picking up a series of ’garments’ as it descends through the heavenly spheres to incarnation, some of which are irrational. But later evidence from Porphyry and Iamblichus indicates that Numenius’ psychology was regarded as distinctive and strongly dualist. Finally, Numenius, like Middle Platonists in general, had no objection to postulating transmigration into animals if a soul became excessively corrupt.

Nursing ethics

Nursing ethics may be defined simply in relation to what nurses do that doctors and others do not characteristically do; or in relation to the nursing perspective on any issues in health care and medicine. More radically, it claims to employ a distinctive conceptual framework, regarding care, rather than cure, as fundamental. Nursing ethics concerns itself with the relationship between 'carer' and 'cared for' and the meanings embedded in that relationship. It is the moral exploration of an illness or disability as a personal life crisis rather than an instance of a biomedical generalization.

The divergence of medical and nursing ethics took its cue from a distinction between curing and caring. Curing, involving diagnosis, treatment and prognosis, was taken to be characteristic of medicine (with surgery as the paradigm), while caring, involving preparation for treatment, maintenance, and recuperation, was characteristic of nursing (with, perhaps, palliative or domiciliary care as paradigmatic). These were soon taken to be more than just two aspects of physical management of patients but conceptually distinct kinds of activity, one directed to a 'distanced' biology-based approach to dysfunctional specimens, or even parts of specimens, of *Homo sapiens*, and the other a humanities-based intimate approach to individual persons with unique life crises. Whereas this distinction is not sustainable as an absolute it does provide enlightening analytic comparisons of emphasis or tendency.

The distinction has continued to develop as a philosophical one and has merged with gender debates. Nursing ethics has taken up the notion of 'care' formulated by Carol Gilligan (1982) and Nel Noddings (1984) (see Feminist ethics §1). The debate is largely an engagement with the 'principalism' founded by Beauchamp and Childress (1979) (see Medical ethics §6). Some nursing ethicists have developed the idea that the 'ethics of care', rooted in a feminine response to life, is a superior alternative to a masculine 'ethics of justice'. Certainly the overwhelming majority of nurses are female, but while some take this as evidence of an advantageous feminine moral attitude others have thought it reflects only political contingencies.

Some insist that rationalistic, abstract and liberal 'impartiality' and 'distance' lead to indifference and unresponsiveness in modern medicine, and expound a contrasting 'partialist' nursing ethics of context, personal engagement and unique human relationships (see Impartiality). Nursing theorists influenced by Gilligan, such as Fry and Watson, take up her suggestion that whereas a principles approach seeks agreement, the caring approach seeks mutual understanding through an exploration of the meaning of a personal crisis (illness, disability, infirmity). Gadow (1980) has a distinctively nursing notion of care in her concept of 'existential advocacy': a true nursing relationship involves helping patients make sense of their life experiences so as to regain some control, clarifying the patients' values so as authentically to exercise their freedom of self-determination. The emphasis on the 'carer/cared for' relationship has led one stream of nursing ethics, influenced by Benner, into phenomenological methods.

Other writers have attempted to integrate principles-based approaches with 'caring relationship' approaches. Beauchamp and Childress, admitting that principles may be insufficient for health care ethics, have responded with a clarification of 'mutual interdependence' and 'emotional response' in the 'ethics of care' and still regard the notion of caring as too undeveloped to be integrated coherently. One empirical study finds no significant difference in the distribution of 'impartialist' and 'partialist' modes of thinking among doctors and nurses and suggests the modes really operate together but at different levels.

The question of a difference between medical and nursing ethics, whether a sharp one or merely one of emphasis and tendency, is carried into questions about which health care issues nurses identify as ethically problematic and how they approach them. Nurse ethicists often do, and *qua* nurses arguably should, select issues which concern nursing activity (the assessment, planning, implementation and evaluation of care) as opposed to medical activity (diagnosis, treatment, prognosis). Such issues would be found in, for example, health promotion and preventative nursing, continuing care of the elderly, and residential and hospice care. Given the intimate and ongoing nature of the nursing process (as opposed to the transitory medical intervention) ethical issues are identified in everyday and routine issues, such as incontinence and toileting, falls among the elderly, and choice of clothing and sleep periods.

Ethically aware nurses may more readily see the human, personal, cultural and social aspects of any issue, whether medical or nursing, such as patient self-esteem and privacy, pain alleviation and comfort, empowering and encouraging self-care, security and general wellbeing. Ethical issues in nursing research may relate in content to clinical nursing (such as wound or bed sore management) or may, in form, approach issues through meanings and relationships employing the methods of ethnography or ‘action theory’.

The considerations above also apply to ethical issues in the organization and professional development of nursing. The themes of ‘nurse autonomy’ and ‘advocacy’ are particularly strong. The first concerns the degree to which nurses can exercise moral choice as employees and as the subordinates of doctors. Thus, professional and contractual obligations may come into conflict, for example, over informing the patient in their interest about a matter the employer may regard as commercially confidential (see Professional ethics); and medical judgment and nursing judgment may conflict, for example, over when to discharge a patient. In these contexts the rights and wrongs of ‘blowing the whistle’ may arise. This may even be entailed by the demand that the nurse act as ‘advocate’ of the patient. The interpretation of this notion is controversial. While it requires that the nurse plead the cause of the patient, it is not always clear whether this is to be given the ‘banal’ interpretation that the patient by definition is someone who needs another to do what they would do if able, or the ‘radical’ interpretation that the nurse must challenge and speak up to defend the patient against any obstacle whatsoever to their autonomy (see Autonomy, ethical).

‘Nursing ethics’ may be taken as a generic term to cover the concerns of all the professions allied to medicine. In midwifery ethical issues emerge from maternal choice, the professional autonomy of the midwife *vis-à-vis* obstetrics, and ‘natural childbirth’. In physiotherapy there are questions around delimiting potentially coercive or unavoidably uncomfortable or even futile procedures, such as chest physiotherapy on terminally ill patients.

Nyāya-Vaiśeṣika

*The Nyāya school of philosophy developed out of the ancient Indian tradition of debate; its name, often translated as 'logic', relates to its original and primary concern with the method (*nyāya*) of proof. The fully fledged classical school presents its interests in a list of sixteen categories of debate, of which the first two are central: the means of valid cognition (perception, inference, analogy and verbal testimony) and the soteriologically relevant objects of valid cognition (self, body, senses, sense objects, cognition, and so on). The latter reflect an early philosophy of nature added to an original eristic-dialectic tradition. On the whole, classical Nyāya adopts, affirms and further develops, next to its epistemology and logic, the ontology of Vaiśeṣika. The soteriological relevance of the school is grounded in the claim that adequate knowledge of the sixteen categories, aided by contemplation, yogic exercises and philosophical debate, leads to release from rebirth. Vaiśeṣika, on the other hand, is a philosophy of nature most concerned with the comprehensive enumeration and identification of all distinct and irreducible world constituents, aiming to provide a real basis for all cognitive and linguistic acts. This endeavour for distinction (*viśeṣa*) may well account for the school's name. Into the atomistic and mechanistic worldview of Vaiśeṣika a soteriology and orthodox ethics are fitted, but not without tensions; still later the notion of a supreme god, whose function is at first mainly regulative but later expanded to the creation of the world, is introduced. In the classical period the Vaiśeṣika philosophy of nature, including the highly developed doctrine of causality, is cast into a rigorous system of six, later seven, categories (substance, quality, motion, universal, particularity, inherence, nonexistence). Nyāya epistemology increasingly influences that of Vaiśeṣika.*

The interaction and mutual influences between Nyāya and Vaiśeṣika finally led to the formation of what may be styled a syncretistic school, called Nyāya-Vaiśeṣika in modern scholarly publications. This step, facilitated by the common religious affiliation to Śaivism, occurs with Udayana (eleventh century), who commented on texts of both schools. Subsequently, numerous syncretistic manuals attained high popularity. Udayana also inaugurated the period of Navya-Nyāya, 'New Logic', which developed and refined sophisticated methods of philosophical analysis.

1 Sources

The basic Vaiśeṣika text is the *Vaiśeṣikasūtra*, ascribed to the legendary founder of the school, Kaṇāda ('grain-eater'; also Kaṇabhuj, and Kāśyapa by clan name). This compilation of some 400 concise and often enigmatic mnemonic sentences contains materials from several developmental stages of the system; substantial parts of it may have been in existence already during the first two centuries AD. Old commentaries are referred to in later works, but have for the most part been lost. Mainstream classical Vaiśeṣika largely goes back to the *Padārthadharmasaōgraha (Compendium of Properties of the Categories)* - also called *Praśastapādabhāṣya (Praśastapāda's Commentary)* - of Praśastapāda (early sixth century), the great systematizer and scholiast of the school. Another compendium from approximately the same period, the innovative *Treatise on the Ten Categories* by Candramati (surviving in Chinese translation), had no lasting impact. The major works of the classical period are commentaries on the *Padārthadharmasaōgraha*: the *Vyomavatī(The Spacious [Commentary])* by Vyomaśiva (ninth century), the *Nyāyakandalī(The White-Flowered Tree of Nyāya)* by Śrīdhara (late tenth century) and the *Kiraṇāvalī(A Sequence of Rays)* by Udayana (early eleventh century). A commentary on the *Vaiśeṣikasūtra* by Candrānanda (probably ninth or tenth century) was published only in 1961; although strongly influenced by the *Padārthadharmasaōgraha*, it preserves a more genuine version of the text than the until then standard commentary by Śaōkara Miśra, the *Vaiśeṣikasūtra-Upaskāra (The Ornament of the Vaiśeṣikasūtra; fifteenth century)*.

At the basis of Nyāya is the *Nyāyasūtra*, ascribed to Akṣapāda. Its earliest preserved commentary, Pakṣilasvāmin Vātsyāyana's *Nyāyabhāṣya (A Commentary on Nyāya)*, dates from the second half of the fifth century. Its subcommentary, the *Nyāyavārttika (A Supplementary Commentary on Nyāya)* by Uddyotakara Bhāradvāja (sixth century), represents a defence and renewal of Nyāya in response to Buddhist logic. Of many commentaries on these two texts, only Vācaspati Miśra I's voluminous *Nyāyavārttikatātparyaṭīkā (A Commentary on the True Intention of the Nyāyavārttika*; tenth century) has survived. It is commented upon by Udayana in his *Nyāyavārttikatātparyapariśuddhi (The Clarification of the True Intention of the Nyāyavārttika)*. Important independently composed treatises of the classical period are Jayanta Bhaṭṭa's *Nyāyamañjarī(A Cluster of Blossoms of Nyāya*; late ninth century) and Bhāsarvajña's *Nyāyasāra (The Essence of Nyāya)*, with the author's own

extensive commentary, *Nyāyabhūṣaṇa (The Ornament of Nyāya*; tenth century). Udayana's *Ātmatattvaviveka (The Discernment of the True Nature/Reality of the Self)* mainly defends the notion of a permanent self against Buddhist criticism, whereas his *Nyāyakusumāñjali (A Handful of Flowers of Nyāya)* establishes the existence of a supreme god. Of Navya-Nyāya works, Gaōgeśa's monumental *Tattvacintāmaṇi (The Jewel of Reflection on the True Nature [of Things]/Reality*; fourteenth century) deserves special mention (see Gautama, Akṣapāda; Vātsyāyana; Uddyotakara; Udayana; Gaōgeśa).

2 Origin and orientation of Vaiśeṣika

The beginnings and development of Vaiśeṣika prior to its classical form are still largely obscure. The most valuable and knowledgeable attempt so far at a comprehensive 'archaeology' of Vaiśeṣika is the brilliant, though necessarily speculative and sometimes intuitive reconstruction of the school's formation by Erich Frauwallner. About thirty years after the publication of his *Geschichte der indischen Philosophie (History of Indian Philosophy)*, volume II (1956), Vaiśeṣika studies experienced a renaissance, and scholars turned again to his stimulating reconstruction. Some developments traced by him have been reconsidered; his evaluation of the original orientation of the school has also become the subject of debate. According to Frauwallner, early Vaiśeṣika is an outstanding example of a philosophy of nature that strives systematically to understand and explain the world out of a pure philosophical urge for knowledge, without mythological, theological or soteriological interests. Within the broader tradition of philosophy of nature in which Vaiśeṣika arose, Frauwallner also locates the materialist schools (see Materialism, Indian school of). Other philosophical schools belonging to that tradition, however, notably Jainism, Nyāya and Mīmāṃsā, combined philosophy of nature with soteriological and ethical teachings. Frauwallner assumes that Vaiśeṣika too, during its development, was influenced by the religious and moralistic tendencies of contemporary philosophies and eventually added a soteriology, still later a theology, to its teachings. These developments he perceives in stark contrast to the school's original spirit and considers them to have had negative consequences for it. Some modern Indian interpreters, notably Anantalal Thakur (1969), also stress the purely scientific attitude of the *Vaiśeṣikasūtra*.

The other extreme lies in ascribing an original and primary soteriological concern to early Vaiśeṣika (for example, Madeleine Biardeau) or a general religious orientation by claiming its main purpose to be the defence of the Vedas and of orthodox ritualism and ethics against heterodox challenges (Jan Houben 1994). Because sources for the school's early history are lacking, it is safer to assume a middle stand, leaning towards Frauwallner's side. The basic orientation of early and even classical Vaiśeṣika is certainly towards cosmology, the systematic and comprehensive explanation of the world, its origin and the processes, natural, psychological, and so forth, occurring through the interaction of its constituents. Some rudimentary soteriology, however, may have been attached already to the early teachings, even if it was an extraneous element of minor importance. The very acceptance of the notion of an individual soul would necessitate in its historical context some ideas about the soul's involvement in rebirth and its possible release from it.

A similar situation can be assumed for those teachings in the epic *Mahābhārata* that have a pronounced character of philosophies of nature. Their predominant topics are the origin and constitution of the world, centring around the concept of the five 'great elements', earth, water, fire/light, wind/air and space/'ether'. The elements are respectively characterized by firmness, moistness, and so on, and, among other qualities, by the 'special qualities' that are the five sense objects, namely, smell, flavour, form, touch and sound, which are sometimes conceived as the emanations of the elements. Various qualities to be subsumed under these five 'special qualities' are enumerated in long and heterogenous lists. All things of this world, including the body and the five senses, are made up of the five elements. The generally strong interest in the empirical human being is manifest in theories about the formation of the body, its constitution by the elements and its internal processes, such as digestion. Attention is also paid to the explanation of cognitive processes. The five senses are recognized as different from their seats, that is, the sense organs; according to the principle 'like grasps like', they grasp the five 'special' elementary qualities and consist of the element which possesses the respective quality. An internal organ or sense (*manas*) functions in non-sensory cognitive processes and rules over the activities of the external senses. Further entities in the world are the individual souls, the sentient and active subjects within the bodies. They are responsible for life, and due to involvement with the sense objects and nescience they become the subjects of transmigration. Time and the cardinal directions appear also as important factors in the world.

It is within the milieu of these teachings that one can situate the beginning of Vaiśeṣika. During its formation they were further developed and refined; in particular, the entities perceived as primary constituents of the world were systematized, some of them subsumed elsewhere, some accorded independent status, and some eliminated, towards an ordered and complete enumeration of irreducible world constituents.

3 Origin and formation of Nyāya

The roots of the Nyāya school are in the ancient Indian tradition of debate (*vāda*). In the Vedic period, priests already held verbal contests as part of ritual, to discover and appropriately formulate the enigmatic true nature of the world and of the rituals themselves. Subsequently, the Upaniṣads refer to religious-philosophical debates at the assemblies of local rulers. The winners were rewarded not only with recognition and fame, but also with material goods and royal patronage. Thus rules of debate had to be fixed, and guidelines were compiled to assure an orderly and fair procedure. They also provided criteria to determine sound and unsound arguments and thus winners and losers. These early guidelines developed into manuals which covered heterogenous points, such as the characteristics of the opponent and composition of the audience with respect to psychological tactics, types of debate, manner of speech, the parts of an argument and their order, means of valid cognition employed in an argument, types of faulty reasons, unfair criticism, and various points of defeat. The central position, however, was occupied increasingly by consideration of the method (*nyāya*) of proof. Epic references to numerous ‘models of method’ (*nyāyatantra*) pronounced by debaters may point to this tradition.

The tradition of debate was closely related to the branch of knowledge or ‘science’ concerned with principled and reasoned reflection (*ānvīkṣikīvidyā*), or even led to its development. Further designations related to this ‘science’ of argumentative corroboration or disproof also refer to its special concern and general method, which, like the term ‘nyāya’, is often rendered as ‘logic’: ‘the science of turning around (in examination)’ (*tarkavidyā*, *tarkaśāstra*), ‘the science of (formal and logical) coherence’ (*yuktiśāstra*) and ‘the science of reasons’ (*hetuvidyā*, *hetuśāstra*).

At first the manuals of debate and reasoned examination may have been formulated without presupposing specific metaphysics, and therefore could be used by different religious and nascent philosophical traditions. However, the central concern with the method of proof led to increasing reflection on the means of valid cognition and logical issues, and eventually certain traditions of debate became associated with certain philosophical outlooks. Further, in the case of Nyāya, the reflection on the *objects* of valid cognition, one of the categories of debate, initiated the inclusion of an early philosophy of nature, similar to the one from which Vaiśeṣika developed, into an originally eristic-dialectic tradition. With the addition of a plain soteriology, the process of the formation of a separate philosophical school was concluded.

4 Ontology: the three older categories

The *Vaiśeṣikasūtra* presents a developed philosophy of nature clad in a rigorous doctrine of categories (*padārtha*, literally ‘meaning of a word’). The six categories fall into two triads, of which the first may historically precede the second: (I) substance, (II) quality and (III) motion; (IV) universal, (V) particularity and (VI) inherence. Further categories, namely potentiality and nonpotentiality, existence (the highest universal) and nonexistence, were introduced by Candramati, but not generally accepted. Nonexistence (*abhāva*), though, increasingly attracted philosophical interest and was finally adopted as a seventh category in the eleventh century (see Negative facts in classical Indian philosophy §5). As elaborated by Wilhelm Halbfass (1992), common to everything comprised by the six classical or seven postclassical categories are the three abstract attributes of ‘is-ness’ (*astitva*), that is, objectivity or factual identifiability, knowability and nameability. This points to the basic endeavour of Vaiśeṣika, the enumeration and identification of what there is in order to provide a real basis for all cognitive and linguistic acts. However, only substances, qualities and motions exist in the fullest sense, that is, as concrete ‘objects’ or ‘things’ (*artha*), because the highest universal, existence (*sattā*, literally ‘being-ness’, ‘real-ness’; or *bhāva*, literally ‘becoming’, but used synonymously), inheres in them. Universals, particulars, inherence and nonexistence are also ontologically distinct and irreducible world constituents; in contrast to the first three categories, they can be substrata only of abstract properties (*dharma*), but not of further ontologically founded entities, including the universal ‘existence’ - that is, they can function as logical subjects (*dharmin*) only.

(I) The category of substance (*dravya*) comprises nine items. The first four are (1-4) the four elements, earth,

water, fire and wind, which exist in the form of eternal atoms and impermanent aggregates. The fifth element, (5) 'ether' (*ākāśa*), functions primarily as the eternal substratum of sound; it is inferred by elimination from the very existence of the quality sound, which requires a substantial support. Because sound can arise everywhere, 'ether' is considered as one and omnipresent. In such qualities, including eternity, 'ether' resembles time, space and the individual souls or selves. (6) Time (*kāla*) is conceived as a timeless, static and inactive substance responsible for our notions of relative position in time and the qualities of temporal remoteness and proximity in limited and noneternal substances. Similarly, (7) space (*diś*) accounts for our notions of relative spatial position and remoteness and proximity in space. The ubiquitous (8) selves (*ātman*) are restricted to individual bodies as the places of their experiences and activities only because their atom-sized and eternal (9) 'internal organs' (*manas*) are connected with a body. However, the self may have originally been considered as having limited dimension, that is, as being contained within the body, and thus capable of motion and physical activity.

The impermanent substances, the objects of everyday experience, are wholes (*avayavin*) consisting of a single element each, with the possible admixture of further elements. These wholes constitute something new over and above their parts (*avayava*), a claim contested especially by the Buddhists. According to the classical theory of causality, the smallest whole is constituted by two conjoined atoms; the first visible whole is the sun mote or triad, composed of three dyads. All further substances are produced by various numbers of larger, visible parts.

(II) The qualities (*guṇa*) are unrepeatable quality individuals, particularizations in time and space of abstract qualities such as colour or flavour. They are ontologically distinct from the substances in which they inhere, but dependent on them as their substrata. Caused in the whole substance by the qualities of its parts, they are destroyed with its destruction. Some qualities inhere in only one substance, such as temperature, colour, flavour and smell, the 'special qualities' of the physical elements. They accumulate in the eternal atoms of wind, fire, water and earth, where they too are eternal: wind possesses only (tepid) temperature, fire (hot) temperature and (bright white) colour, and so on. Other qualities inhere in more than one substance simultaneously, for example, the 'common qualities' conjunction and separation, important factors in causation, and number (above one). The list of seventeen qualities in the *Vaiśeṣikasūtra* further enumerates the 'common qualities' dimension (ranging from atomic size to large size to infinite size, that is, ubiquity), separateness, and remoteness and proximity (in space and time). Further 'special qualities', namely of the self, are cognition, pleasure and pain, desire and aversion, and effort, all impermanent. It is by effort that the omnipresent self, incapable of movement itself, initiates mechanistically conceived psychological and physical processes. To these seventeen seven more are added by Praśastapāda's time: weight, fluidity, viscidity, disposition (comprising momentum, elasticity, and impressions responsible for recollection left in the self by cognitions), merit (*dharma*) and demerit (*adharma*), and sound, the 'special quality' of 'ether'.

It is not observed that, for example, colours possess further colours. Moreover, if they did, this would result in an infinite regress. Motion, on the other hand, is only observed with corporeal things. Therefore, all qualities are devoid of further qualities or motions.

(III) The five items in the category of motion (*karman*) go back to a classification of human actions: throwing upwards and downwards, bending and stretching, and going. Subsequently all other types of motion, inhering in atoms, the 'internal organs' and impermanent substances, are subsumed under 'going'; motion itself is momentary and inheres in only one substance at a time. It plays an essential role in the atomistic-mechanistic world view of Vaiśeṣika, for example, in causation, to effect the conjunction between substances to produce new wholes (see Causation, Indian theories of §5), and in the mechanistic explanation of natural processes, macrocosmic (for example, meteorological) and microcosmic (for example, digestion, birth and death, cognition), often effected by 'the invisible' (*adṛṣṭa*), a force also at work in the ritual and ethical context (see §7) and later identified with merit and demerit inhering in the self. A complete chapter of the *Vaiśeṣikasūtra* is devoted to mechanics in the broadest sense, although a science of mechanics, as in ancient Greece, did not evolve.

Like qualities, motions are ontologically separate from, but dependent on, supporting substances; they are also devoid of qualities or further motions.

5 Ontology: the younger categories

(IV) Universals (*sāmānya*, literally 'commonness', 'sameness'/'similarity') inhere in substances, qualities and

motions; they are the hypostasized generic properties responsible for the connection of various entities with the same concept or designation and for their conception as belonging to the same group. Contrary to qualities, they are one, eternal and repeatable; for example, the one universal 'cow-ness', characterized as having horns, a dewlap, a tail, and so on, resides fully and simultaneously in every cow alive and is unaffected by the demise of an individual cow. Although dependent on substances, qualities and motions as their substrata, universals provide them with their generic character and identity. The highest universal is 'being-ness' or existence, which is common to substances, and so on; the lower or specific universals (*sāmānyaviśeṣa*), such as 'substance-ness', 'colour-ness' and 'hot-ness', effect not only a notion of recurrence and inclusion of their substrata in one class, but also of their exclusion from entities belonging to other classes. Special attention is devoted to the differentiation of real universals from mere abstract properties (*dharma*); by Udayana's time, criteria have been developed to discern real from unreal universals (see Universals, Indian theories of §2).

(V) The elusive category particularity (*viśeṣa*) or ultimate particularity (*antyaviśeṣa*), as clarified by Halbfass (1992), comprises, according to Praśastapāda, the 'factors of irreducible individual identity'. These particularities assert timeless, unchangeable generic and numeric identity for permanent entities, notably the individual atoms, selves and 'internal organs'; they allow accomplished Yogis to discern individual atoms of earth with their special powers of perception, for example. Particularities also inhere in the unitary substances 'ether', time and space. For Candramati, they alone possess particularity, inasmuch as their generic identity cannot be asserted by specific universals: there are no other entities in their class to be included.

(VI) Inherence (*samavāya*, literally 'concourse') is the unitary eternal entity responsible for the connection of distinct entities which are in a relationship of support and supported and cannot exist separately. It causes the notion that something is 'here', that is, resides in something else; for example, a product or whole, such as a cow, inheres in its causes or parts, such as horns, dewlap, tail, and so on. The entities belonging to different categories are joined by way of this dependent residence to form the actual complex things of this world. At the base are the substances; due to inherence the universals existence, substance-ness and, for example, cow-ness reside in a substance, as do its qualities, such as white colour, and motions, that is to say going. White colour and going are again related to existence and their respective generic characters by inherence.

The ontology of classical Nyāya closely resembles that of Vaiśeṣika. This is due to their similar background regarding philosophy of nature (see §3). The historically later chapters of the *Nyāyasūtra* basically presuppose and assert classical Vaiśeṣika ontology in their discussions of the means and (soteriologically relevant) objects of valid cognition. The Vaiśeṣika categoriology, however, was fully adopted and further developed starting with Uddyotakara only. The lasting points of difference are mainly of a scholastic nature; a major one concerns the mode of colour change in fired pots. According to Vaiśeṣika, the fire destroys the pot up to its atoms, which lose their original dark colour due to the heat; subsequently the heat causes a new colour in them, and thanks to 'the invisible' a similar pot is built up again, with a new reddish colour. Nyāya, on the other hand, allows tiny interstices in the structure of the pot into which the fire can intrude; its heat then causes a colour change of the *whole* pot, which remains structurally intact and the same throughout the process. The independently minded thinker Bhāsarvajña argued for revisions of the categories, but without lasting impact. In his innovative *Padārthatattvanirūpaṇa (Examination of the True Nature/Reality of the Categories)*, the sixteenth-century Navya-Naiyāyika Raghunātha Śiromaṇi eliminates 'ether', time and space, for example, as separate categories by ascribing their roles to God, and introduces new categories such as the moment and potency.

6 Epistemology, logic and dialectics

The very composition of the *Nyāyasūtra* demonstrates the traditionally central interest of Nyāya in these areas. Among the sixteen categories of debate in Nyāya, the means or instruments of valid cognition (*pramāṇa*) occupy the first place. The larger number of *pramāṇas* current at the time is reduced to four: (1) perception (*pratyakṣa*), (2) inference (*anumāna*), (3) analogy or comparison (*upamāna*), and (4) verbal testimony (*śabda*). In Vaiśeṣika, the *pramāṇas* are treated under the category of quality because cognition is a 'special quality' of the self. Cognition is divided into knowledge and nescience; knowledge includes perception and inference as *pramāṇas*, as well as recollection and the intuitional cognition of omniscient seers. Analogy and verbal testimony are subsumed under inference. Both schools distinguish between, for example, perception as a means and the resulting knowledge (*pramā*); in the controversy about the intrinsic or extrinsic validity of the resulting knowledge they

adopt the latter position. They further hold that the *pramāṇas*, although of different natures and modes of functioning, can converge on the same object, contrary to the view that their objects are exclusive (see Epistemology, Indian schools of §2; Knowledge, Indian views of §3).

(1) *Perception* (as *pramā*) arises from a contact between self, sense, 'internal organ' (*manas*) and object (= perception as *pramāṇa*). The atom-sized, swiftly moving 'internal organ' serves as the regulating link between the omnipresent self and the elementary-materially conceived senses (see §2); this explains the denial of the simultaneity of different sense perceptions and cognitions in general. The senses either move out to their objects, as do the visual rays, or are approached by them. A differentiation into six types of contact was necessitated by the introduction of Vaiśeṣika categoriology to account for the perception of, say, colour, which as a quality cannot be the substratum of a further quality conjunction (see Sense perception, Indian views of).

Large substances that possess colour are perceptible by vision and touch as something over and above their qualities. Some thinkers even maintained that their perception without any qualities is sometimes possible. Generally they appear with other substances, qualities and motion as their qualificands; due to the perception of their specific universals they appear qualified as similar to others of their class. At first, only the 'special qualities' of the self were assumed to be perceptible by a specific contact between the 'internal organ' and the self; from them its existence had to be inferred. However, several thinkers also claimed its self-perception through this contact. The other perceptible qualities and motion are perceived only when inhering in perceptible substances; this perception is further dependent on perception of their specific universals, whereas the perception of universals, lacking further universals, merely follows that of their substrata. Inherence is only inferable in Vaiśeṣika, whereas in Nyāya it is perceived as qualifying its relata, like nonexistence.

Unlike Dignāga, certain Naiyāyikas (the Ācāryas, commentators on the *Nyāyavārttika*) maintained that perception can be conceptual, that is, that language/concepts in the form of impressions may be part of its causal complex and may influence its content. In doing so, they gave up the realistic principle, defended by the Vyākhyātṛs (commentators on the *Nyāyabhāṣya*), that the external and internal objects of perception have to be equivalent.

(2) *Inference* depends on perception and is threefold: (a) 'as before', (b) 'as the rest' and (c) 'observed from similarity'. The *Nyāyasūtra* provides no further explanations here, and all the commentaries seem unreliable. Albrecht Wezler (1969) has argued convincingly that parallel passages in early Buddhist texts preserve the appropriate examples: (a) refers to recognition by some special mark, (b) to inductive generalization and (c) to analogical reasoning. Vātsyāyana provides two alternative explanations for each type, none of which fits the *sūtra*'s terminology smoothly. For instance, (b) is explained as inference either from effect to cause or by elimination.

Perhaps the original intention of the *sūtra* was lost because inference was just one among many topics in manuals of debate (see §3) and numerous attempts to characterize it were current; for example, the *Vaiśeṣikasūtra* refers to four situations in which entities can function as sound reasons or signs to infer others: A is connected (to B), A is related by inherence (to B), A is related by inherence to the same thing (as B), and A is in contradiction (to B). As a *pramāṇa*, inference appears in the *Nyāyasūtra* in a category different from the members of proof. Only after Vasubandhu merged inference and proof did the former become central in Indian philosophy. Subsequently, the two are distinguished in Nyāya and Vaiśeṣika only in terms of purpose, as 'inference for oneself' and 'inference for another'. The old notions of inference are largely forgotten, and the structure of proof becomes basically that of inference, dominated from Praśastapāda and Uddyotakara onwards by the concept of three characteristics (trairūpya) of a valid reason and refined by Trilocana's concept of an essential relation between probans and probandum (see Inference, Indian theories of §§4-6).

The members of proof are proposition, reason, illustration (by similar or dissimilar examples), application and conclusion. For example:

Sound is impermanent,
because it is produced,
like a pot (which is produced and impermanent).
Sound is like that (that is, produced).
Therefore, it is impermanent.

A dissimilar example would be the self, which is not produced, and is permanent.

For Nyāya, there are twenty-four types of sophistries with which to attack such an argument unfairly, and twenty-two ways of losing a wrangle (‘points of defeat’), of which the use of fallacious reasons is most important philosophically. Fallacious reasons appear also as a separate category, which consists of the deviating or inconclusive reason, the reason contradicting a tenet, the reason which is the same as the original issue, the reason which is the same as the probandum, and the reason which has passed the proper time (for enunciation). The *Vaiśeṣikasūtra* also mentions two fallacious reasons (‘unestablished nonstatements of a reason’), the unreal/untrue and the doubtful. Subsequently, all of them are reinterpreted, sometimes drastically, and refined within the framework of *trairūpya*. The fallacious reasons of Vaiśeṣika are equated with the first two of Nyāya (in reverse order), and Praśastapāda adds a third type, the reason which does not lead to any decision; it subsumes the too specific reason, a subtype of the Nyāya inconclusive reason. The last two items in Nyāya, in their updated forms, are adopted also in later Vaiśeṣika.

(3) By *analogy* one knows the connection of a certain designation with an object. Analogy as *pramāṇa* is hardly ever used in philosophical discussion; it is employed very narrowly and should not be confused with cognition of similarity, which is obtained by perception and inference.

(4) *Verbal testimony* is defined as instruction by a reliable person and includes everyday linguistic communication and scriptures. Correct reasoning cannot be in conflict with the Vedic scriptures; yet their argumentative corroboration, even validation, is proclaimed to be the central task of Nyāya. In practice, however, Nyāya is more concerned with the nature of articulated sound *per se*, its duration, and the relationship between words and their referents. On all these issues Nyāya held its own views and strongly opposed not only Buddhists, but also Mīmāṃsakas and Sāōkhyas (see Testimony in Indian philosophy).

7 Soteriology and ethics

Both schools claim that knowledge of their categories leads to release (*apavarga*). In Nyāya, Vātsyāyana narrowed this knowledge to adequate understanding of the twelve soteriologically relevant objects of valid cognition; appearing as a separate category, they indicate the more harmonious integration of soteriology in early Nyāya than in Vaiśeṣika (see §§2-3). The *Nyāyasūtra* proclaims that with the absence of wrong understanding (which absence is caused by adequate understanding of the categories), the three faults (*doṣa*) - craving, aversion and delusion - disappear, and subsequently the linguistic, mental and physical activity instigated by them ceases; the cessation of activity means that a result of activity will not arise and thus not effect a new life for it to be experienced by the acting subject. Consequently - suffering being found nowhere but in life - no suffering will occur; release, which is defined as final and complete liberation from suffering, is attained. According to the *Vaiśeṣikasūtra*, liberation (*mokṣa*) technically consists in the absence of all conjunctions concerning the self and involving it in pleasure and pain, and in the nonmanifestation of a new body for it. In liberation, all ‘special qualities’ of the self vanish. This idea of liberation evoked strong criticism, especially from Vedāntists, who compared it to the undesirable state of an unconscious stone.

Although the faults or moral defilements (*kleśa*) may be natural to the self, release is possible, just as atoms of earth can lose their natural black colour when a pot is fired (see §5). Furthermore, because the faults are conditioned by wishful expectative thinking relating back to previous experience, their naturalness is doubtful, and they can be wiped out by elimination of this conditioning through adequate understanding. Adequate understanding is initiated by a preceptor and attained by contemplation and yogic exercises repeatedly practised in quiet secluded spots, accompanied by perfection of the self with the help of general and specific rules of restraint (*yama*, *niyama*). The grasp on knowledge has to be trained incessantly; here friendly debate with knowledgeable disciples, teachers, fellow students and others striving for salvation is recommended. Even wrangle and dispute involving mere criticism of the other party, the other two types of debate, can serve to protect and strengthen the ascertainment of the true nature of things. Unlike the *Nyāyasūtra*, the *Vaiśeṣikasūtra* proclaims that orthodox, ritual-dominated merit (*dharma*) accomplishes uplift in subsequent lives and liberation. The elusive sixth chapter treats orthodox ethical and ritual conduct, specifying means that effect a certain purpose or result which is called ‘the invisible’ (*adṛṣṭa*; see §4) and that are conducive to uplift. However, in contrast to the initial proclamation, the activity of merit and demerit is stated as the cause of the self’s involvement in rebirth, which highlights the complex and problematic integration of soteriology and ethics. The notion of a supreme god, whose function

within the atomistic-mechanistic worldview of Vaiśeṣika is mainly regulative, is found first in Praśastapāda's work.

Viśvanātha Pañcānana (17th century) *Bhāṣāpariccheda* and auto-commentary *Siddhāntamuktāvalī*, trans. Mādhavānanda, *Bhāṣā-Pariccheda with Siddhānta-Muktāvalīby Viśvanātha Nyāya-Pañcānana*, Calcutta: Advaita Ashrama, 1954. (Translation of the most popular syncretistic manual.)
Wada, T. (1990) *Invariable Concomitance in Navya-Nyāya*, Sri Garib Dass Oriental Series 101, Delhi: Sri Satguru Publications.(A clear introduction to basic Navya-Nyāya concepts, with translations and explanations of important passages on the invariable concomitance between probans and probandum in inference.)
Wezler, A. (1969) 'Die "dreifache" Schlussfolgerung in *Nyāyasūtra* 1.1.5' (The 'Threefold' Inference in *Nyāyasūtra* 1.1.5), *Indo-Iranian Journal* 11: 190-211. (Clarification of the most probable original meaning of the *Nyāyasūtra*'s definition of inference, by comparison with early Buddhist texts.)
Wezler, A. (1982) 'Remarks on the Definition of "*yoga*" in the *Vaiśeṣikasūtra*', in L.A. Hercus *et al*. (eds) *Indological and Buddhist Studies: Volume in Honour of Professor J.W. de Jong on his Sixtieth Birthday*, Canberra: Faculty of Asian Studies, 643-86. (Argues that the sections on yoga, liberation and yogic perception were not part of the original *Vaiśeṣikasūtra*, but half-hearted concessions to contemporary philosophical tendencies.)

Nygren, Anders (1890-1978)

Nygren hoped to recover the uniqueness of Christianity from the impurities introduced by the attempts of nineteenth-century liberal theology to free it from metaphysical speculation and confessional dogmatism. He aimed to do this by grounding all religion in an analytic philosophy of religion which would enable him to stress the objective character of Christian theology in contrast to the arbitrariness of confessional theology. He achieved international influence by his claim in Agapē and Eros (1930-6) that the uniqueness of Christianity is love in the sense of agapē, *as opposed to Platonic* eros.

Like many of his theological contemporaries in Sweden, Nygren sought to show the legitimacy of theology as a university subject. While a professor at Lund (1924-48), he argued that theology could withstand positivistic criticism of the sort made by Axel Hägerström (§5), whose attack on Hegelian-inspired perspectives sought to include theology in its anti-metaphysical cleansing of Swedish philosophy. Nygren, like Hägerström, accepted Kant's criticism of a rational theology based on the traditional proofs of God's existence, but rejected Kant's reduction of religion to ethics (see Kant, I. §11). Like Schleiermacher (§7), he insisted that religion is a distinctive perspective, as are the perspectives of reason, practice and ascetic value. But Nygren does not base religion on a specific religious experience, which would make it primarily subjective. Rather, religions are an obvious historical fact. Nygren viewed philosophy in a Kantian fashion, as a critical study of the necessary conditions of meaning. Theology as a university subject could be justified as a historical critical study of the meaning of Christianity, and so could be utterly objective, intersubjective and testable (unlike confessional theology, which rests on revelation alone, as does the neo-orthodoxy of Barth and Brunner).

By the time of Nygren's last major work, *Meaning and Method* (1972), philosophy had taken a linguistic turn, with which he felt at home. Drawing upon Wittgenstein's *Philosophical Investigations*, he was able to develop his philosophy of religion in its idiom. He stressed context as crucial to the meaning of language, and held that philosophy could clarify the differences and relations between basic contexts of meaning. He also added what he called 'the context of contexts', consisting of four great questions which in *Agapē and Eros* he had called 'fundamental motifs'. He claimed that these larger contexts are simply given in human life, and summarized them as the question of truth, which is institutionalized as science; the question of good and evil, and right and wrong, institutionalized as law and ethical traditions; the question of the beautiful, institutionalized in art; and the question of the eternal, institutionalized as religion.

Nygren argued that philosophy of religion is the specification of the fundamental presuppositions that concern human encounters with the eternal; this for him is not an abstraction, such as timelessness, but that which breaks into time and enables us to see that life is not subject merely to the conditions of finitude. He did not perform this task, but indicated four elements in the existential confrontation with the eternal, which occur wherever there is religion: an unveiling, a disquieting judgment, a reconciliation, and a vital fellowship. These elements are merely formal and are specified only from a knowledge of the content of actual religions, but they enable one to specify the logical place of religion in relation to other fundamental perspectives, and to clarify confusions in religion that result from mixing contexts.

Nygren maintained that the task of theology is the study of concrete religions. He called his method 'motif research' and supposed it applicable to all historical research. One could discover the basic notion around which all the historical phenomena revolved, and which provided the context of meaning for those phenomena. The answer each religion gives to the fundamental question of the eternal is its motif. For Judaism it is law, for Christianity it is *agapē* and for Hellenic civilization it is *eros*.

Nygren contrasted the distinctive Christian conception of love, which he called *agapē*, with the Platonic notion, which he called *eros* (see Love §2). All *eros* is egocentric and acquisitive, whereas *agapē* springs wholly from within and takes no account of worth. The former is human, the latter divine. Nygren claimed that, as fundamental motifs, these should not be mixed, but that historically they had been, above all by Augustine. Only with the Reformation was the original New Testament notion of *agapē* restored. However, this thesis has been countered, and Nygren's characterization of both *agapē* and *eros* challenged (Burnaby 1938; D'Arcy 1954; Markus 1955).

Oakeshott, Michael Joseph (1901-90)

Although Michael Oakeshott was in his own time a lone figure in a philosophical world dominated by Oxford analysis, he has come to be recognized as the most notable British political philosopher of the twentieth century. He is best known for his view that political activity is neither purely empirical nor the application of ideas, but 'the pursuit of intimations'. His image of culture as a conversation between different kinds of understanding has been widely accepted. Oakeshott first became celebrated in attacking what he called 'rationalism' in the Cambridge Journal (which he edited) in 1947. Oakeshott's rationalist is a restless political meddler who believes that politics is putting ideas into effect. The fullest statement of his political philosophy is On Human Conduct (1975), in which the modern state is understood as a tension between civil and enterprise association. Exploring the idea of a civil association is perhaps Oakeshott's most notable contribution to political philosophy.

1 Modes of experience

Michael Oakeshott was born at Chelsford, Kent, and attended St George's School, Harpenden. He studied history at Gonville and Caius College, Cambridge, and became a fellow after two years spent visiting German universities and as a schoolmaster. During the Second World War he served in the British army. In 1952 he succeeded Harold Laski as professor of political science at the London School of Economics, a post from which he retired in 1969.

The early Oakeshott was confidently classified as an idealist on the basis of *Experience and its Modes* (1933) and some contemporaries early on were tempted to pigeonhole and ignore him. Susan Stebbing reviewing the work in *Mind* thought that it merely reworked Bradley. A.J. Ayer said of Oakeshott's conservatism that 'it's all in Burke'. One reviewer as late as *On Human Conduct* (1975) merely assimilated him to Wittgenstein. All of this was to miss a highly original philosophical intelligence which explored the idea of the state more deeply than any of his contemporaries.

In *The Voice of Poetry in the Conversation of Mankind* (1959) Oakeshott provided the best short synoptic view of his philosophy, and also launched a famous image: human life is an endless conversation between different 'voices'. Practice, science, history and poetry are voices, while philosophy is 'the impulse to study the quality and style of each voice', and to reflect upon the relationship of one voice to another. The philosopher's reflections, however, make no specific contribution to this conversation, for only those with a specific conceptual point of view have anything to contribute. Philosophy is in particular distinct from practice, and can make no direct contribution to it, though Oakeshott occasionally allows that it may have such a virtue as 'hindering irrelevance'.

In *Experience and its Modes*, however, Oakeshott had appeared to give philosophy a rather grander role: it was the pursuit of 'what is ultimately satisfactory in experience'. The modes, by contrast, were forms of experience limited or 'arrested' by their logical dependence upon constitutive assumptions. Practice, for example, is experience understood in terms of desire and frustration - *sub specie voluntatis*. Science cultivates a mechanical world understood in terms of quantity. History is the world understood in terms of its pastness. Philosophy explores these conditionalities in the search for a concrete understanding of experience as released from the abstract or fragmentary character of the modes. It is both what is ultimately satisfactory in experience, and also recognized as a somewhat perverse enterprise: most of the time, men understandably prefer 'the empty kisses of abstraction'.

Oakeshott is evidently hard to classify. A consistent allegiance in his work is to a Platonic conception of philosophy as exploring the conditionalities of experience in order to discover its postulates - but Oakeshott's philosopher has no timeless realm to contemplate. Again, he seems to reveal the grand vision of the philosophical vocation found in Hegel, yet he combines this vision with an underlabouring insistence on philosophy's irrelevance to the world which links him to British empiricism, especially Hobbes. What is certainly clear is that he took philosophy to be the activity of thinking through the conditions of some human activity, purging it of contingency and merging its conclusions and its presuppositions in an ideal character revealing the logic of our understanding. His intellectual life consisted in successive inquiries of this kind - the first published in *Experience and its Modes*, a second in *The Voice of Poetry in the Conversation of Mankind* (where the fundamentals are revisited in order to accommodate art to the system of modes) and finally and most magisterially in the first two essays of *On Human Conduct*. Let us first, however, consider this same intellectual exercise performed on a smaller scale in essays written around 1946. They are to be found in *Religion, Politics and the Moral Life* (1993).

2 Epistemology

The basic error about political philosophy, he argued in 'The Concept of a Philosophy of Politics', was to think that it consisted merely in the *application* of some already established philosophy to the field of politics. Oakeshott's objection to this procedure is that 'application' is altogether too mechanical a process to have any place in philosophy. Oakeshott denied that philosophy could provide anything with foundations - one of the doctrines which has led Rorty and others to assimilate him to modern forms of pragmatism (see Pragmatism). Nor did it provide criteria of action, for practice could never achieve the coherence of a philosophical concept.

Oakeshott's ontology is sceptical without being in any way solipsistic. The world is composed of images, or 'intelligibles'. A thing is what it is imagined to be, but might be any number of other things. Concepts such as 'thing' or 'fact' are merely verdicts or judgments about some object of experience which always appears to the understanding in one specific guise or other, never as any kind of basic datum. Oakeshott frequently reverts to the doctrine of the *Meno* in which understanding always begins with something already in some degree understood, and moves on to other understandings, without ever achieving finality. Although he contrasts practical skill with rationalist notions of technology, Oakeshott rejects any notion of a basic level of common sense (frequently identified with practice) to which all controversies can be assimilated. The aim of *Experience and its Modes* is to show the impossibility of assimilating one mode to another, and drawing the conclusion that irrevelance, or *ignoratio elenchi*, is the most crippling form of error. In *The Voice of Poetry* he complains that the voice of practice is becoming a bore in the modern world because it is becoming strident and tries to dominate the conversation. Part of the reason for this is that practice and science can seem to be mutually assimilable because they have some names in common - such as 'fact'.

History also suffered from the kind of uncriticial monism which took historical facts to be the same kind of logical entity as facts in science and practice. A major thread in Oakeshott's career was his lifelong devotion to thinking out the minimal epistemological conditions of historical understanding. One effect was to banish the idea of cause from the field. He recognized, of course, that historians often affirmed causal relationships, but he interpreted this as a rhetoric of emphasis within a process in which the aim was to compose the circumstantial understanding available from the records so as to answer to the question: what happened? Only this could provide the intelligibility allowing us to understand why it happened. Such intelligibility was the most we might expect from history, but it was also the only manner in which human life itself might be explained.

3 Political philosophy

In his last major work, Oakeshott typically started all over again. *On Human Conduct* begins with a long essay on theorizing human conduct. Whereas nature may be understood in terms of process, the human world is self-conscious and procedural. The basic confusion of the social sciences has been a failure to clarify the distinction between, as it were, a wink and a blink.

The 'engagement' of understanding is, he tells us, a continuous, self-moved, critical enterprise of theorizing. It emerges out of 'misty intimations of intelligibility'. We distinguish 'goings on' in terms of some characteristic; identification is specification in terms of an ideal character composed of characteristics. At this point in Oakeshott's phenomemology of understanding a more coherent system of thought, which he calls a 'conditional platform of understanding' has emerged: every 'going on' is what it is in respect of being understood in terms of an ideal character specified as a composition of characteristics. Wittgenstein took a similar view in construing ideas in terms of 'family resemblances'. A theorist may, however, treat an identity not as a verdict to be accepted, but as an invitation to make such an identity more intelligible, and this can only be done by seeking to understand it in terms of its conditionality.

The voices and modes of Oakeshott's earlier formulations have here given way to a more pluralistic scheme. The theorizer may 'fish' for the understandings available from these conditional platforms of understanding. Yet the irony of all theorizing, Oakeshott remarks, is its propensity to generate, not an understanding, but a not-yet-understood. Thinking thus leads the theorizer towards higher platforms of understanding concerned with exploring the postulates of that activity itself.

Turning to human conduct, Oakeshott finds that it is a set of 'goings on' which exhibit intelligence. We necessarily

act in terms of some specific practice, and a practice is a language of self-disclosure. Inseparable from action in the moral dimension is what Oakeshott calls 'self-enactment' in which conduct reveals the self to itself and to others.

In the second essay, Oakeshott analyses the state, though the word itself is kept at bay (see State, the). Feeling that the modern vocabulary of politics had been seriously corrupted, he reinstates Latin terms (such as *civitas*, *lex* and *respublica*) as technicalities. The task is to distinguish the 'civil condition'. It certainly is not to be found in those transactions of reciprocal desiring which belong to the social rather than the civil world. A second 'categorially distinct mode of association' is revealed in 'agents related in the joint pursuit of some imagined and wished-for common satisfaction' (1975a: 112): what Oakeshott called 'enterprise association'. The state as an enterprise association is a view almost irresistibly invoked by the familiar question: what is the end or purpose of the state? But enterprises are voluntary, while the state is compulsory.

There does remain, however, a distinct form of association corresponding to the civil condition. It is 'relationship in terms of the conditions of a practice'. The *cives* of a civil association relate to one another in nothing else but a recognition of the authority of rules, in respect of which they are all equal. They are thus not the comrades of an enterprise association, but much more like the speakers of a language, whose intelligibility derives from conforming to its rules. This is a formal relationship in that the rules do not specify any particular conduct; they are merely 'adverbial qualifications' of whatever a member might choose to do. But although formal, these rules constitute a practice which is moral in the basic sense of not being instrumental to the enjoyement of specific satisfactions.

Here then is an analysis of the forms of human association so intricate that Oakeshott created a complex vocabulary and style in which to express it. It leaves any attempt at synopsis far behind.

Objectivity

Objectivity is one of the central concepts of metaphysics. Philosophers distinguish between objectivity and agreement: 'Ice-cream tastes nice' is not objective merely because there is widespread agreement that it is true. But if objectivity is not mere agreement, what is it? We often think that some sorts of claim are less objective than others, so that a different metaphysical account is required of each. For example, ethical claims are often held to be less objective than claims about the shapes of middle-sized physical objects: 'Murder is wrong' is held to be less objective than 'The table is square'. Philosophers disagree about how to capture intuitive differences in objectivity. Those known as non-cognitivists say that ethical claims are not, strictly speaking, even apt to be true or false; they do not record facts but, rather, express some desire or inclination on the part of the speaker. Others, dubbed subjectivists, say that ethical statements are in some sense about human desires or inclinations. Unlike the non-cognitivist, the subjectivist views ethical claims as truth-apt, but as being true in virtue of facts about human desires or inclinations. Some philosophers, referred to as anti-realists, disagree with both non-cognitivism and subjectivism, and attempt to find different ways of denying objectivity. Quietists, on the other hand, think that there are no interesting ways of distinguishing discourses in point of objective status.

1 Non-cognitivism and subjectivism

Intuitively, an ethical claim such as 'It is right to help those in distress' is less objective than a claim such as 'The table is square'. What does this intuition amount to? Non-cognitivists, such as Ayer (1936), Blackburn (1984) and Gibbard (1990), focus on the semantic function of the two claims. 'The table is square' has the function of asserting that a fact obtains in the world. If that fact obtains - if the table is square - then the claim is true; if not, it is false. Thus 'The table is square' is apt to be true or false: it is truth-apt. On the other hand, the non-cognitivist views 'It is right to help those in distress' as having a different semantic function: despite appearances, its function does not consist in asserting that a fact obtains in the world. It is not truth-apt; rather, it expresses an inclination, desire, or some other non-cognitive attitude of the speaker, in the same way that 'Hurrah!' or 'Boo!' merely expresses a favourable or unfavourable attitude. This is why some versions of non-cognitivism are called 'expressivism'. Ethical claims are less objective than claims like 'The table is square' since the latter are genuine truth-apt assertions, whereas the former are not. Non-cognitivists have viewed ethical claims as not objective in this sense for various reasons: because of widespread disagreement over moral matters, because moral facts seem 'queer' or 'odd', and because of the normative character of moral discourse.

There are problems with this way of capturing differences in objective status. Consider the inference:

1 If lying is wrong, then getting little brother to lie is wrong.
2 Lying is wrong.
3 Getting little brother to lie is wrong.

According to non-cognitivism, 'Lying is wrong' and 'Getting little brother to lie is wrong' are not truth-apt. But the inference is intuitively *valid*. And to say that an inference is valid is to say that the truth of the premises guarantees the truth of the conclusion. How can non-cognitivism explain the validity of the inference, given that it denies that (2) and (3) are even apt to be true? Relatedly, the non-cognitivist has a difficulty with (1). What sense can be made of a conditional whose antecedent and consequent are not truth-apt? Non-cognitivism has had difficulty in finding satisfactory answers to these questions (Hale 1993).

Subjectivists take a different tack. They admit that 'It is right to help those in distress' is truth-apt, that its sincere utterance makes a genuine assertion. They thus avoid the sort of difficulty outlined above. But if an ethical claim genuinely asserts that a fact obtains, what sort of fact is it? According to the subjectivist, it is simply a fact about the person making the claim: when I say 'It is right to help those in distress' I am asserting that I desire to help them. Ethical claims are truth-apt, but the facts they assert to exist are facts about us, our desires, inclinations or subjective states. When I say 'It is right to help those in distress' I literally *mean* 'I desire to help those in distress'. This contrasts with claims like 'The table is square' which, though truth-apt, are not analysable in terms of facts about human subjectivity. In this sense, 'The table is square' is the more objective.

Subjectivism has difficulty in accounting for moral disagreement. If Jones says 'It is right to help those in

distress' and Smith says 'It is wrong to help those in distress', they are disagreeing with each other, indeed contradicting one another. But if Jones means 'I (Jones) desire to help the unfortunate', whereas Smith means 'I (Smith) do not desire to help the unfortunate', there is no contradiction. So in what sense do they disagree?

Subjectivism may try to deal with this by focusing on a wider range of desires than those possessed by the individual who utters the statement. 'It is right to help those in distress' literally means 'Most people desire to help the unfortunate', so that its content is spelled out in terms of intersubjective agreement in desires. But this also faces problems. If it were true, it would be a contradiction to say that helping the unfortunate is right even though most people do not desire to do it. But it is not a contradiction, so even this wider subjectivist analysis must be flawed.

2 Anti-realist views of objectivity

Suppose we admit that two types of claim are truth-apt and yet do not have an anthropocentric subject matter. Do we have to view them as equally objective? Anti-realists, such as Wright (1986, 1992) and Dummett (1978), think not. They try to show how differences in objectivity can be captured, without adopting either non-cognitivism or subjectivism. How can we distinguish between 'It is right to help those in distress' and 'The table is square' if we allow that both are truth-apt, and that neither is susceptible to a subjectivist analysis? One way would be to develop an analogue of the distinction between primary and secondary qualities, the locus classicus for which is Locke (1689) (see Primary-secondary distinction; Secondary qualities). The standard example of a secondary quality is colour, while shape is usually held to be primary. What is involved in the claim that redness, for example, is a secondary quality? The idea is that there is a close relationship between facts about certain of our subjective states and statements like 'The mailbox is red'. In order to explain this relationship, we need to explain the notion of a best judgment. A judgment that an object is red is best when it is made in conditions that are optimally good for appraising whether or not the mailbox is red. These conditions could be specified very roughly as those that obtain out of doors, in the shade, at lunch time on a lightly overcast summer afternoon. To say that redness is a secondary quality is to say that our best judgments concerning the redness of objects determine the extension of the concept red. The extension of a concept is the class of things to which that concept can correctly be applied. So our best judgments about whether objects are red *determine* which class of objects the concept red can properly be applied to. In contrast, a primary quality like squareness is one whose extension is determined independently of facts about best judgments concerning squareness. Best judgments in this case merely detect an independently determined extension.

This way of saying how 'The mailbox is red' is less objective than 'The table is square' is different from the subjectivist analysis. To say that redness is secondary is not to say that 'The mailbox is red' literally means that 'If conditions were best, we would judge that the mailbox is red'. The claim is the weaker one, that our best judgments determine whether the mailbox falls in the extension of red. The proposal that redness is a secondary quality can therefore avoid the problems associated with subjectivism. And since it does not deny that 'The mailbox is red' is truth-apt, it avoids the problems associated with non-cognitivism. One way, then, to claim that ethical claims are less objective than claims like 'The table is square' is to argue that ethical qualities such as right, wrong, good and bad are secondary rather than primary.

According to the anti-realist, there can be more than one way of saying that one type of claim is less objective than another. Even if we cannot show that ethical qualities are secondary, there might be other ways of contrasting ethical claims with different claims. One way concerns what Wright (1986) calls 'objectivity of truth'. This notion of objectivity features prominently in Dummett's discussions of realism. To say that a class of statements exhibits objectivity of truth is to say that '[they] may be fully intelligible to us even though resolving their truth-values may defeat our cognitive powers (even when idealized)' (Wright 1986: 5). Their truth might be 'evidence-transcendent': they are determinately either true or false, even if we are in principle incapable of citing evidence for or against them. Take Goldbach's Conjecture (that every even number greater than two is the sum of two primes), or some claim about past happenings in some far distant galaxy. We understand these claims, but we are in principle incapable of resolving their truth-values. This gives us one way of claiming that mathematical or cosmological claims are more objective than claims about morals or comedy. There is little temptation to think that claims about the moral status of an action, or about the comic quality of a joke, may in principle transcend our best cognitive efforts. There are no difficulties akin to those affecting non-cognitivism and subjectivism: there is no

denial of truth-aptitude, nor an assignment of an anthropocentric subject matter.

3 Objectivity of meaning and quietism

The main danger for the anti-realist story about objectivity comes from Wittgenstein's rule-following considerations (RFC). According to Wright, the RFC endanger the objectivity of meaning. This is the view that 'the meaning of a statement is a real constraint, to which we are bound… by contract, and to which verdicts about its truth-value may objectively conform, quite independently of our considered opinion on the matter' (Wright 1986: 5). The meaning of a statement imposes requirements on what counts as correct use of the statement, which determine what uses are correct and incorrect independently of any opinions we may subsequently form. The problem is that if the RFC destroy the idea that meanings are objective in this sense, they thereby threaten the various ways in which anti-realists attempt to draw comparisons concerning objectivity. For example, Wright believes that objectivity of truth implies objectivity of meaning. If the RFC force us to reject objectivity of meaning, they also force us to reject objectivity of truth. And if no discourses possess objectivity of truth, appealing to failure of objectivity of truth will be useless for drawing comparisons between discourses. Likewise, since the truth of any statement is a function of its meaning together with facts about the world, rejection of objectivity of meaning may entail that all qualities are secondary. The possibility of appealing to the primary-secondary distinction in order to draw a contrast will be endangered. In short, the RFC seem to threaten us with quietism about objectivity: the view that no principled, metaphysically interesting contrasts concerning objectivity can be drawn.

Anti-realists try to find ways of avoiding quietism, while retaining their interpretation of the RFC (Wright 1992: Ch. 6). Note that some philosophers, such as McDowell (1995), think that there is a different way in which quietism about objectivity can open up. McDowell does not view the RFC as threatening the objectivity of meaning. So the relevance of the primary-secondary distinction and evidence-transcendent truth is not threatened in the direct manner envisaged in the previous paragraph. The distinctions the anti-realist wishes to draw can still be drawn: instead, what the RFC threaten is the idea that there is any interesting metaphysical *point* to be made by appealing to the distinctions in the first place. For example, it might be argued that the thought that the anti-realist primary-secondary distinction is of metaphysical relevance depends upon a conception of detecting or tracking facts that the RFC display to be untenable.

Obligation, political

The problem of political obligation has been one of the central concerns of political philosophy throughout the history of the subject. Political obligations are the moral obligations of citizens to support and comply with the requirements of their political authorities; and the problem of political obligation is that of understanding why (or if) citizens in various kinds of states are bound by such obligations. Most theorists conservatively assume that typical citizens in reasonably just states are in fact bound by these obligations. They take the problem to be that of advancing an account of the ground(s) or justification(s) of political obligation that is consistent with affirming widespread obligations. Other theorists, however, anarchists prominent among them, do not accept the conservative assumption, leaving open the possibility that the best theory of political obligation may entail that few, if any, citizens in actual states have political obligations.

Much of the modern debate about political obligation consists of attempts either to defend or to move beyond the alleged defects of voluntarist theories. Voluntarists maintain that only our own voluntary acts (such as freely consenting to the authority of our governments) can bind us to obedience. Because actual political societies appear not to be voluntary associations, however, voluntarism seems unable to satisfy conservative theoretical ambitions. Some individualists turn as a result to nonvoluntarist theories of political obligation, attempting to ground obligations in the receipt by citizens of the benefits governments supply or in the moral quality of their political institutions. Others reject individualism altogether, defending communitarian theories that base our political obligations in our social and political roles or identities. Individualist anarchists reject instead the conservative ambitions of such theories, embracing a voluntarism which entails that most citizens simply have no political obligations.

1 The problem

The problem of political obligation has been central to political philosophy from the earliest recorded philosophical texts to the most recent. While the actual term ‘political obligation’ is of relatively recent vintage, arguments as old as those of Plato’s early dialogue, *Crito* (*c*.395-87 BC), are clearly intended to address some version of the problem. Political obligations, as these are commonly understood, are the moral obligations (or duties) of citizens to support their countries, governments or political and legal institutions. They are usually taken to include at least the obligation to obey the laws of the land (or the just laws) and are often thought to include also further obligations of loyalty and ‘good citizenship’.

The problem of political obligation, then, is that of understanding the force and nature of these moral bonds and, most importantly, of understanding when (or if) and for what reasons (if any) the members of various kinds of states are subject to them. Peoples’ political obligations constitute the core of the moral relationship that exists between them and their polities, and they are thus closely related to such corresponding concepts as the legitimacy or *de jure* authority of the state (see Authority; Legitimacy). The question here is not: under what institutional requirements, backed by force, do we stand? Rather, political philosophers ask whether in addition to (or conceivably because of) the threat of institutional coercion, blind political habits and emotional grounds for obedience, there are also strong *moral* reasons for supporting and complying with the demands of our laws, governments or states.

The problem of political obligation has usually been understood conservatively. So understood, it is the problem of finding a sound justification for our intuitive conviction that most citizens (or at least those in certain familiar kinds of states) do in fact have political obligations. Conservative theorists will thus be centrally concerned with providing a suitably ‘general’ account of political obligation, one that shows why all citizens of good states have the obligations we suppose they have. But the problem can also be understood without any conservative commitments, so that an account’s lack of generality is not necessarily a defect. On this understanding, the theorist’s job is simply to give as full as possible an account of political obligation, without any special concern for justifying our pre-theoretical beliefs about the subject. Thus, an anarchist theory (which denied the existence of any political obligations) might on this latter understanding still constitute a successful (that is, valid, nondefective) theory of political obligation.

Theories of political obligation can be (roughly) divided into four groups, the most basic division being that

between ‘communitarian’ and ‘individualist’ theories. Communitarians typically maintain that our very identities are constituted in part by our roles (such as ‘membership’) in political society and that our political obligations are tied conceptually to, and follow trivially from, these roles. Individualists maintain, by contrast, that we should not in this way think of ourselves as essentially political beings; instead, our political obligations rest not on our institutional roles, but on contingent relations between political associations and ourselves (such as our consent to them or our receipt of benefits from them).

Individualist theories of political obligation can be further divided into two classes. ‘Voluntarists’ ground people’s political obligations in their personal performance of politically significant voluntary acts, such as promises or contracts to obey, consent to authority, or free acceptance of benefits from a political scheme. ‘Nonvoluntarist’ (individualist) theories hold that no such voluntary performance is necessary for political obligation. Simple nonvoluntary receipt of benefits may bind us, for instance, or the moral qualities of a government may bring it under more general moral duties that require us to give it our support.

The fourth group consists of the anarchists. ‘Anarchist’ theories deny altogether the existence of political obligations. While the inspiration for an anarchist view can itself be either individualist or communitarian, anarchism rejects the conservative assumptions of the standard theories in both categories.

None of these four approaches to the problem of political obligation is new. Indeed, three of them are suggested in various passages in Plato’s *Crito* (see Plato §6). There, Socrates argues first that he must obey the state’s commands because it has made him what he is (50d-e), suggesting a communitarian derivation of obligation from his politically-constituted identity. But he later contends as well (in a more individualist fashion) both that his obligations stem from a tacit promise to obey (51e-53a) and that the care and benefits provided for him by the state bind him to obedience (51c-e) (suggesting, respectively, voluntarist and nonvoluntarist positions).

2 Communitarian theories

Drawing their inspiration from Plato, Aristotle, Hegel and Wittgenstein, communitarians argue that our plans and purposes, our values, and thus essential aspects of our very identities, are given us by the roles we play within linguistic, social and political communities (see Community and communitarianism). It is as a result misleading to think (as individualists do) of our moral relation to the state as somehow optional or contingent. Citizen and state are not like unrelated contractors in economic negotiations, as voluntarists seem to maintain. Nor do our political obligations rest on externally derived moral duties, as nonvoluntarists claim. Rather we have obligations to obey the rules of our communities because this is part of what it means to be members of those communities. Who we are in our social contexts tells us what obligations we have. To ask for any further explanation of political obligation would be to ask the unintelligible question: why should our lives be regulated by what makes us what we are (Green 1882). The proper account of political obligation looks to justifications that are internal to our practices, not external to them.

Communitarians whose sympathies are Wittgensteinian typically advance some version of a conceptual argument: that political obligation is conceptually tied to membership in a particular political society, and that membership is not voluntary, optional or contingent upon external justifiability (Pitkin 1965-6; Horton 1992). Comparisons are often drawn between political obligations and family obligations (which are similarly nonvoluntary) or obligations to friends and colleagues (which we often ‘acquire’ rather than choose, and which we continue to have even when we do not want them). Lest we think these analogies appeal only to nonliberal theorists, it should be noted that they have motivated at least one well-known political liberal to offer an account of political obligation as an ‘associative’ or ‘communal’ obligation (Dworkin 1986).

Communitarians whose sympathies are more Aristotelian or Hegelian tend to modify or add to these conceptual arguments. Political community, they argue, is essential to human flourishing and the development of human moral capacities, such as agency or autonomy or self-conscious valuation. As such, not only are our political communities owed obedience and support (as long as they encourage this development); we have also an obligation to belong to and facilitate political communities (Taylor 1979). On this view, because our political relations contribute essentially to our identities as moral agents and autonomous choosers, these relations cannot themselves be thought of as freely chosen or as dependent on moral principles that bind us independent of our political roles. While feminist political philosophy has not focused centrally on the problem of political obligation,

most feminist accounts are also broadly communitarian or 'contextual' in character (Hirschmann 1992).

3 Voluntarist theories

Individualist theorists deny that we are essentially political beings, that our political obligations are a simple function of our identities as socially constituted persons (Green 1988). The political realm is a contingent, nonessential aspect of human life (even if it is also a quite typical feature of it), and our unchosen social and political roles cannot simply be assumed justifiably to define our moral responsibilities. This denial of the communitarian's 'political naturalism' is most strongly stated (or assumed) by voluntarists. The classical individualist theories of political obligation were mostly voluntarist in character, and nearly every voluntarist theory prior to the twentieth century was some variant of a consent or contract theory of political obligation (see Consent; Contractarianism §5). The terms of the modern debate about political consent were set most clearly by Locke (see Locke, J. §10). According to Lockean consent theory, political obligations are grounded in the personal consent of individual members to the authority of their government or political society. This consent can be either express (as in direct agreements or contracts to obey, oaths of allegiance, and so on) or tacit (indirectly given by other behaviour that signifies consent). But voluntary, intentional consent of some sort is necessary for political obligation; government without popular consent is tyranny (Locke 1690). Consent theories tend to focus on tacit (implicit, indirect) consent, given the apparent paucity of express consenters in modern political communities. Favourite candidates for acts of tacit consent on which our political obligations might rest include continuing to reside in a state one is free to leave, freely taking benefits from the state, voting in democratic elections and accepting adult membership in a state.

The intuitive appeal of consent theory (in its respect for each person's free choices) is considerable and its history is long and distinguished. But the theory has throughout that history been plagued by fundamental complaints that it is not in fact applicable to real political life. Real political societies are not voluntary associations and real citizens seldom give even tacit consent. Indeed, all of the acts alleged to constitute tacit consent to government are typically performed without any intention to consent to government authority at all; and they are often performed unfreely, simply because of the high cost of alternatives, such as emigration (Hume 1739-40). But if morally binding consent must be intentional and voluntary, such facts seem to force us to the conclusion that few citizens of actual states count as even tacit consenters and that consent theory cannot adequately account for the political obligations we believe these citizens to have (Simmons 1979).

Consent theorists have responded by specifying further conditions that must be satisfied if 'government by consent' is to be achieved (Beran 1987) and by insisting that genuine, binding consent is only given by full involvement in the political life of a participatory democracy (Pateman 1979). These responses, of course, involve to a certain extent giving up conservative ambitions in thinking about political obligation. But a more conservative move within the voluntarist camp has been to surrender instead the idea of consent as the paradigm ground of political obligation. Thus, fairness theories of political obligation maintain that our obligations are owed as reciprocation for benefits accepted from the workings of our cooperative legal and political institutions (Hart 1955). Consent to these institutions is not necessary for being obligated to support them and abide by their rules. Rather, it is enough that we freely accept the benefits that flow from the cooperative sacrifices of others; for to do so while refusing to do our own parts in the scheme would be to take unfair advantage of those who cooperated in good faith.

Fairness theories, however, have also been subjected to steady contemporary criticism. One prominent early proponent of a fairness account has since rejected it (for reasons followed by many others), arguing that citizens in actual political societies seldom freely accept the benefits their societies provide, but instead merely receive them without real choice (Rawls, J. §1). And others have challenged the portrayal of modern political communities as large-scale cooperative schemes, sufficiently like small-scale cooperative enterprises to give rise to similar obligations of fairness (Simmons 1979). As a result of these criticisms, many individualist theorists have concluded that voluntarist accounts of political obligation are unpromising, and they have turned instead to nonvoluntarist theories.

4 Nonvoluntarist theories

The distance from voluntarist to nonvoluntarist (individualist) theories of political obligation can seem at first

glance quite small. There are, for instance, nonvoluntarist versions of the fairness theory, according to which it is not our free acceptance of the benefits of government that grounds our obligations, but rather our (possibly nonvoluntary) receipt of certain cooperatively produced goods that are of great importance to both individuals and societies (such as the benefits of law enforcement and national defence) (Klosko 1992). And there are also nonvoluntarist gratitude theories, which view political obligation as a special case of the obligation to reciprocate in an appropriately grateful fashion for benefits conferred on us by others (Walker 1988). Such nonvoluntarist benefit (or reciprocation) theories obviously have much in common with voluntarist fairness theory. But the theoretical distance of such accounts from voluntarism is in fact considerable. For political obligations, instead of resting on what individuals choose to do (as in voluntarism), are now taken to rest on what merely happens to those individuals and on the virtues of the institutional arrangements under which they live. This is to locate the moral heart of political relationships in a quite different area than that identified by the voluntarist.

The distance from voluntarism is similarly deceptive in the case of hypothetical contractarian accounts of political obligation. Our obligations, on this approach, are determined not by our personal consent to (or contracts with) our political authorities, but by whether we (or some suitably described, more rational or more neutral version of us) would have agreed to be subject to such authorities in an initial choice situation (Rawls 1971; Pitkin 1965-6). Hypothetical contractarianism, because it centrally utilizes the idea of contract or consent, may at first seem to be just a development of or a variation on voluntarist consent theory (and its advocates often present it as such). In fact, however, hypothetical theories are no longer concentrating on individual choice or on specific transactions between citizen and state, but instead on the quality of the political institutions in question. Hypothetical contractarians ask whether our laws or governments are sufficiently just or good to have been consented to in advance by rational parties, in an initial specification of their terms of social cooperation. What matters here is not choice or individual history, but the nature and quality of government (see Contractarianism §5).

This emphasis on quality of government is also present in utilitarian theories of political obligation, despite their constant opposition to contractarian views. According to utilitarians, our political obligations are based in the (direct or indirect) utility of support for and compliance with government (Hare 1976). Because obedience generally promotes social happiness, it is typically obligatory. But, of course, obedience only promotes social happiness if the specific laws or government in question are well-framed, utility-producing devices; our political obligations are thus derived reasonably directly from determinations of governmental quality.

The well-known contemporary objections to utilitarian moral theory (Rawls 1971) are only one reason why critics have found unconvincing the utilitarian account of political obligation. Like all nonvoluntarist (and communitarian) theories, utilitarians accept birth and benefaction within certain kinds of political communities as sufficient to justify political bonds. Critics worry that this misses the transactional, bilateral character of legitimate cooperative relationships, which in political cases should involve citizen and state jointly committing themselves to acceptable arrangements.

5 Anarchist theories

Anarchism comes in many forms (see Anarchism). Variants range from communist to libertarian (from Karl Marx to Lysander Spooner). Some anarchists deny the very possibility of a legitimate state, while others deny only the legitimacy of existing states. Some urge the destruction of existing states, others only selective disobedience to them. But all forms of anarchism are united in rejecting the conservative assumption that most citizens have political obligations.

It is illuminating to recall that much of the force of communitarian, nonvoluntarist fairness and voluntarist fairness theories of political obligation derives from the perceived failure of consent theory. Consent theory has been attacked as inapplicable to real political societies and alternative theories have been preferred for their superior ability to explain our obligations. But it is important to see that this attack rests squarely on a conservative approach to the problem of political obligation. If the conservative assumption is abandoned, consent theory no longer appears defective. Rather, it can be taken to specify the true grounds of political obligation, grounds that are simply not satisfied in actual or possible states. Voluntarist anarchism thus re-emerges as an interesting theoretical possibility.

Classical anarchism (of both communitarian and individualist varieties) recommended the abolition of the state.

Late twentieth-century philosophical anarchism merely denies the existence of (widespread) political obligation, usually on voluntarist grounds, without making any revolutionary practical recommendations. Some philosophical anarchists have argued on a priori grounds that the authority of the state is inconsistent with individual autonomy (Wolff 1970). Others have argued only that existing states fail to satisfy the voluntarist requirements for political obligation (Simmons 1979). Both forms, however, have been attacked for failing to appreciate the overall force of multiple contributing grounds for political obligation (Gans 1992).

Observation

Observation is of undeniable importance in the empirical sciences. As the source of information from the world itself, observation has the role of both motivating and testing theories. Playing this role requires more than just opening our eyes and letting nature act upon us. It requires a careful attention to the information conveyed from the world so that an observation is meaningful. Scientific observation, in other words, is more than a physical act of sensation; it must be an epistemic act as well, with sufficient meaning and credibility to contribute to knowledge. A report of an observation, therefore, must be more than a 'Yes, I see'. It must describe just what is seen, 'I see that ________'.

This obligation to make observation relevant to theory suggests that there is an essential influence of background theories on the observations themselves. The theories we believe or wish to test tell us which observations to make. And describing the results of observations, that is, bringing out their informational content, will always be done in the language of the conceptual and theoretical system already in place. For these reasons, observation is said to be indelibly theory-laden. And the influence of background beliefs is even greater in cases of indirect observation where machines, like microscopes and particle detectors, are used to produce images of the objects of observation. Here, the reliability of the machines, and hence the credibility of the observation, must be based on a theoretical understanding of the interactions that are the links in the chain of information.

The influence of theory on observation is often seen as a threat to the objectivity of the process of testing and verification of theories, and hence of science in general. If theories are allowed to, indeed required to, select their own evidence and then to give meaning and credibility to the observations, the testing process seems to be unavoidably circular and self-serving. Observation that is theory-laden would guarantee success. But a look at the history of science shows that it does not. There are plenty of cases of observations that are used to disconfirm theories or at least undermine the theorist's confidence. Perhaps there is a kind of observation that is not influenced by scientific theory and can serve as a common, objective source of information to put theories to a rigorous and meaningful test. Or perhaps all scientific observation does bear the influence of background scientific theories, but not necessarily of the theory the observation is being used to test. This independence between the theories that support an observation and the theory for which the observation serves as evidence can break the circle in the process of testing and perhaps restore objectivity.

1 The role of observation

Empirical sciences, whether they are natural sciences like biology, geology and astronomy, or social sciences like psychology and anthropology, make claims that are contingent on what is going on in the world. Non-empirical enterprises like mathematics and logic aspire to what must be true of the world and to what things are possible in the world. But the goal of science is between these two extremes; it is to describe what is in fact true of the world and what does in fact happen. This requires some contact with the actual world and some information from the particular objects of interest themselves. This is the role of observation.

Observations in science are essential both to stimulate the formation of theories and to regulate the testing of theories. In the role as stimulus, observation of perplexing or surprising events will prompt questions of why these things happen, and thereby lead to theoretical explanations. Recurring phenomena call for an understanding of the principles of organization and unification, the theories, to make sense of the observations. And the observation of similarities among phenomena, as Newton noticed similarities in the events of a falling apple and the orbit of the moon, suggest the formation of a unifying theoretical account. In these ways and more, observation can initiate and guide the preparation of theory.

A proposed theory, a hypothesis, can then be tested by being used to make predictions of what will be observed under specified conditions. Actually doing the observations is then an essential part of testing and verifying the theory. Various models of this process of testing and confirmation have been proposed and advocated, differing in the nature of the relation between theory and observation (see Confirmation theory). These models are all alike though in that they require some relation, some contact between theory and observation.

The importance of observation in science is of course because of the supposition that it is the source of information

from the world itself - unlike theory, that begins as information from the minds of scientists. Observation is intersubjective, public and accessible to anyone willing to have a look. This is the reason to expect that observation will provide a source of agreement, a common ground of information to arbitrate disagreements between differing theoretical accounts. Observation must be the source of facts, if anything is, and must provide the objective foundations of science, if anything can.

Whether observation can fulfill of these weighty expectations is itself an issue of disagreement among scientists and philosophers. Understanding the role of observation in science and its potential to be objective or foundational requires a look at the details of what observation must be like in order to contribute to scientific knowledge, and the details of what it is in fact like in the activities of actual science. The questions to ask are these: can observation be a source of agreement to decide between differing theories? Does it in fact play this role in science? And is observation a source of objective information about the world?

2 Informational content

To play the role as stimulus and evidence for scientific theories, observations must fulfil some basic, informational requirements. To serve as evidence, that is, to be a meaningful influence on a theory, an observation must be *of* something that is relevant to the theory. Scientific observation must be informative in the sense of being an observation *that* something is the case. It must be more than just a physical act of sensation; it must be an epistemic act with sufficient meaning and credibility to contribute to knowledge. Credibility is achieved only with some assurance that the observation has been done with care and precision, and in conditions that are conducive to accuracy. And a meaningful observation must be one described in a language that is relevant to the theoretical knowledge it is meant to challenge, change or re-enforce.

An effective way to attend to the informational content of an observation and to its epistemic status is to focus on observation reports rather than on the physical act of perception. The useful question to ask of an observational contact with the world is not simply, ‘do you see it?’, but the more revealing, ‘what do you see?’ or ‘do you see that this is that?’ Answers to these questions, that require more than a nod, give the full description of the observation. These observation reports are the most basic empirical data in science. Even if the report is private, a report to oneself, a useful observation must be presented in an informational form, observing, for example, that the sky is blue, because undescribed sensations can have no impact on theory. Undescribed sensations cannot serve as evidence in science. They neither motivate nor test theories.

This emphasis on language motivates positivists to attempt a neat dichotomy between the observational and theoretical vocabularies of science (see Logical positivism §4). Whether or not this sort of distinction can be made, and whether it has any significance for the structure of scientific knowledge, will be discussed in §6, below. The analysis of observation language, though, rather than simply the physical act of observation, accurately acknowledges that observation in science is more than simply opening one’s eyes and having a look. It is an important and careful activity whose epistemic value depends on what is observed and in what way. And these are assessable only of a meaningfully described observation, one with assertive informational content.

3 Theory-laden observation

The informational requirements as described above lead directly to the concern that observation in science is essentially theory-laden. Observation that is relevant to background knowledge will necessarily bear an influence from background knowledge. If this is true, that observation is influenced by theory, then observation loses its natural innocence. The activity of observation is not a passive acceptance of ready-made information (in the sense of ready-described and ready-justified) given by the objects of interest.

There are three distinct ways that theories can influence observations and that what we see can be dependent on what we think.

For one, background knowledge and the theories we have in mind are the source of authority in deciding what observations to make. Gathering data in science is neither comprehensive nor random, and it is a theoretical understanding of the world that directs our attention to what is important to observe and measure. This is not to suggest that advocates of theories seek out and report only the observations they are confident will reflect favourably on their theory. There is a difference between selecting the important tests and selecting rigged tests,

and while the persuasion of theory can determine which observations to perform, it cannot determine how they will turn out. Only the act of observing can do that.

Another way to think of the theoretical impact in selecting observations is to note that what we observe of the world is always just a small sample of the whole thing, and it is important to be sure it is a representative sample. To be representative a sample must be relevantly diverse, and issues of relevance must always be settled under the influence of some theoretical understanding or other. Testing the effects of some drug, for example, may require observations of people of various ages, weights, medical histories, and so on. But the sample does not have to be representative of different hair colours or preferences in flavours of ice cream, because our understanding of physiology does not regard these as relevant to the effects of drugs. Thus a good sample is one that has been done in light of current background knowledge.

A second influence that theories can have on observation is in assessing the credibility and reliability of the observation report. Scientific observations are acceptable only if they are carefully done. Conditions must be correct, in order to reduce the chances of distortion, and the propriety of conditions is often prescribed by theory. This is particularly apparent in the case of machine-aided observations (see §7). A microscope, for example, is an acceptable tool in science because there is good reason to think that the image produced is an accurate view of the specimen. The good reason is based in theories of optics describing how the microscope works. This theoretical support is rarely explicit in the use of microscopes or the claims of microscopic observation, but it is a source of credibility that must be available in the scientific community. Scientists do not accept the images produced by just any machine, only those they know to be reliable. And even when no machines complicate the observation, the pragmatics of acceptability of observation reports are still leveraged by theory and background knowledge. If an observation report threatens a well-entrenched theory, it is common to look first for a mistake in the observation. This use of theory to edit observation is simply the manifestation of the high standards expected of scientific evidence.

The third aspect of complicity between background knowledge and observation is in giving meaning to the evidence. An observation must be of something that is relevant to theory and so it must be described in a language that makes contact with theory. The observation must be fitted into the system of theoretical concepts. The necessary promotion from a merely physical act of sensation to an epistemic act of observation takes place under the authority of the theories in our background knowledge. To a physicist, for example, the streaks in a cloud chamber are indicative of the passage of subatomic particles. The streaks mean particles, and it is only at this informative level that the observation functions as evidence, useful for making an impact on theory. And it is only under the influence of theory that the description as particle tracks is possible.

Taken together, these three ways in which theories guide observations lead to the notion of ‘theory-laden observation’ (see Duhem, P.M.M.; Hanson, N.R.). The claim is that this is an essential aspect of science and scientific evidence, and not simply a lazy or suspicious way that science gets done by conniving scientists. To say that observation is theory-laden is to focus Kant’s more general claim, that experience without concepts is blind, on the case of science.

4 Using theory-laden observation

Theory-laden observation has serious implications for scientific method and the role of objectivity in science. If all observation bears the imprint of some theory or other, then the results of observation are not pure information from the objects in the world themselves, nor will they necessarily be data that are shared and of universal agreement among scientists. Persons with different theoretical backgrounds may well judge different observations as important and credible, and because of this, hold their theories to different standards. They may even give different meanings to the same perceptual event, and thus draw different conclusions from seemingly the same tests. This poses an immediate threat to objectivity in the testing of theories. If observations cannot provide a common standard against which to test competing theories, those theories may be incommensurable, leaving us with no reasonable way to rate one more likely to be true than the other (see Incommensurability; Underdetermination).

It would be a mistake to think that theory-laden observation is a guarantee that empirical testing will always come out positive and in support of the theories being tested. The history of science is full of examples in which observations went against theory. An interesting case is the solar neutrino problem. According to theory, the sun,

like all other stars, is fuelled by nuclear reactions occurring at its core, reactions that produce neutrinos. The neutrinos ought to be detectable on the earth. The observation of neutrinos is enormously complicated and indirect, and it is profoundly influenced by theory. Nonetheless, the results of observations have been bad news for the theory being tested, the claim of nuclear reactions in the sun. Not nearly as many neutrinos as predicted have been observed. Thus, complicity between theory and observation does not necessarily compromise the testing process in the sense of guaranteeing a supportive outcome.

It is important to confront the threat to objectivity in the light of the details of each particular case of observation in science. A general analysis of the nature of observation and evidence may be enough to show that there is some theory complicity in scientific observation, but beyond that we should ask specifically which theories are involved in any particular case. Perhaps the theories that influence an observation are independent of the particular theory the observation is meant to test. In such a case, there is no circularity in the testing process and hence no threat to objectivity. A look at specific cases might also show that the requisite conceptual ingredient in observation does not rely on the theories that we take to be the currency of science but only on some specifically perceptual background knowledge. If the background knowledge is simply common sense, then the worry about theory-ladening is of little concern to science. Observation in this case can provide data of common consent, useful for settling issues of dispute between competing theories.

Studying actual cases of observation in science can also show whether theories supply a tacit influence over observations, or if observers and those who make use of observation reports are aware of the theoretical contribution in an explicit interpretation of perception. If there is this awareness, the conceptual or theoretical influences can perhaps be abstracted away to reveal a perceptual core. The question will then become whether or not these purely perceptual data have sufficient informational content to be useful as scientific evidence.

5 Indirect observation

Many observations in science are physically indirect in the sense that the observer does not interact immediately with the object itself. Intermediate interactions are required to convey information of the object to an observer. The most obvious cases of indirect observation involve tools that enhance our powers of perception, from a simple magnifier, to a compound telescope, to an enormous bubble chamber. Using such machines, scientists report the observation of objects such as the moons of Jupiter, alpha particles, or even events in the universe just seconds after the Big Bang. There are also cases of indirect observation that do not involve instruments, cases in which the object of observation has left a natural imprint on what can be directly perceived. In this sense, fossils are an image of life in the past, and striations in bedrock show the movement of glaciers (see Geology, philosophy of §1).

All of these cases of indirect observation have in common that the information from the object of interest is mediated by a more-or-less lengthy causal chain from object to scientist. The multiple interactions can impose a physical influence on indirect observation, much as theoretical complicity adds a conceptual influence. And there is an obvious correlation between the two in that more physical complication in an observation is likely to require more theory to keep track of the flow of information.

The image produced in an indirect observation may, in some cases, not even resemble the object that is allegedly observed. Audible clicks of a Geiger counter could be the final stage in the observation of a beta-decay event or the passage of a cosmic ray. The length of a column of mercury in a thermometer allows us to observe the temperature of some other object. But this may be stretching the concept of observation too thin, having come so far from the original expectation of a source of manifest and intersubjective information from the objects themselves. Such highly indirect observation that demands overt interpretation draws the question: do these events even count as being observation?

Answering this sort of question is complicated by the realization that indirectness of observation is a matter of degree, depending on the length and complication of the chain of interactions from the object of observation to the final image. This realization clarifies the important questions to ask of indirect observation. Is the degree of physical removal of the object epistemically significant in the sense that a longer journey makes the information less reliable and makes the event somehow less of an observation? Is there a cut-off, a way to mark an indirect link between observer and specimen as too long or too complicated to count as an observation?

6 Observability

A distinction between what can and what cannot be observed is crucial to an empiricist philosophy of science. Observability is epistemically significant insofar as observation is the foundation of testing and verification of scientific claims (see Demarcation problem §5). The theme of empiricism is that scientists are justified in believing that what they claim about observables is true, but not justified in what they claim about unobservables. There is no denying that the stuff of the world behaves *as if* it is composed of atoms, but that is no reason to believe that it really *is* composed of atoms (see Fictionalism; Scientific realism and antirealism §3). Only by observing can we have reason to believe, and so only of what is observable can we hope to have justified belief.

Empiricism incurs an obligation to supply the criteria for distinguishing between observables and unobservables. This might seem as easy as opening our eyes and seeing what we can see, but observability cannot be decided on the basis of observation, since what is observable is not always observed. Furthermore, what has not been observed is not necessarily unobservable. In fact, anything that is worth looking for has the status of being unobserved but observable. Planets around distant stars, for example, are worth looking for because, being relevantly similar to the planets we see in our solar system (for example, being large and solid), they are observable, though none has been observed. The famous Michelson-Morley experiment to measure the earth's motion through the electromagnetic ether was definitive in its results only by considering the ether to be in some indirect way observable. Since it was observable but not observed, the conclusion was that the ether simply did not exist. Had it been judged to be unobservable there would have been no surprise at the null results. In all cases there will be some antecedent conceptual reason to think that an object is observable, in at least an indirect way, and hence worth looking for.

Observability is not an intrinsic feature of the object or event in question. It is a relational property, observable-to-us, and so it is subject to change if the human capacity to perceive or to go places in the universe to have a look changes. This underscores the fact that observability is intended to have *epistemic*, not *ontological* significance. The empiricist is not claiming that what is unobservable does not exist. Rather, what is unobservable is such that we have no justification in claiming that it exists or that it does not. Justification can of course change, as observability can change.

Any significant distinction between what counts as observable and what does not must acknowledge the complication of the act of observation itself. Observability cannot be merely a function of the perceptual limitations of human observers, since observation must be more than merely a physical perceptual event; it must be an informative epistemic event. Nor can observability depend on being independent of theory if all observation is to some degree influenced by the observer's theoretical background.

There is a potential confusion in this issue of observability, as to whether it applies to the entities of science or to the language of science. It is in the best interest of empiricism to focus on the observability of the entities themselves rather than on the language, since how we describe something will always be influenced by our conceptual and theoretical background, but whether or not we see something is just a fact of our perceptual prowess. A child may not be able to describe the planet Venus as a planet or as Venus in particular, but they can surely see it when directed to the proper location in the sky. This strategy of deciding observability of things, independent of their description in language, threatens the informational requirements of observation. Undescribed observations cannot function as evidence and cannot contribute to scientific knowledge. That is why children and others who lack sufficient training in the conceptual background of scientists cannot step right up and do science, no matter how good their eyesight. Noting the need for informative observation, the issue of observability is going to have to involve some aspects of language and its theoretical associations.

Drawing a distinction between observables and unobservables is further complicated by the cases of indirect observation. It would be difficult to argue that any intermediate instrumentation whatsoever disqualifies an image from being a genuine observation, since viewing the world through a pane of glass or eye-glasses is surely observing the world. But there is little difference between this and using a magnifying glass, and so if what can be seen through a window is observable then so is what can be seen through a magnifier. And this begins a continuum of indirectness with no clear break between what ought to count as observable and what ought not. If the single lens of a magnifying glass enhances our powers of observation and expands the domain of what is observable, then why not the same for a microscope or a telescope, both of which are just a series of magnifiers stacked together? Why not an electron microscope, which does with electrons just as an optical microscope does with light? And so

on. The challenge is to draw a line between what counts as observation and what does not in a way that is not arbitrary and that bears the epistemic significance required of empiricism.

7 Reliable observation

One can acknowledge that there is no sharp boundary between what is observable and what is not, yet still maintain that observability is of great epistemic importance. There are clear cases, after all, of things that we can observe, that the sky is blue for example, and equally clear cases of things that we cannot, that the 'up' quark has an electric charge of $+2 \setminus 3$. The colour of the sky is clearly observable, while the electric charge of a quark is not. And we have a higher level of justification for claims about the colour of the sky than we do for claims about the charge of a quark, precisely because of the difference in their observability. Similarly, in cases of machine-assisted observation such as a cloud chamber, there is a clear sense in which we observe the streaks in the chamber and from these we infer the presence of particles and subatomic events. The features of the streaks are more immediate to our perception, and for this reason, claims about the streaks are more reliable than are claims about the particles. Thus, observability, though not a sharp demarcation, is nonetheless significant in evaluating the justification for scientific claims.

At this point it may be advisable to consult science itself to understand differences of observability and their significance to the status of scientific entities and statements. This does not mean simply adopting the language of science and counting as observable whatever scientists say they observe. It requires an understanding of each scientific case of observation to see what, according to the scientific description, is going on. Science can provide a description of the causal chain and the flow of information from a putative object of observation to the observer, and can in each case reveal which theories are involved in giving meaning and credibility to the observation. A scientific account of the physical indirectness of an observation will detail not only the length of the interaction chain, but the reliability of the passage of information through each link. Understanding the interactions themselves shows that in each case there is some information that can and some information that cannot be conveyed. The physics of quarks, for example, indicates that while such properties as electric charge and mass can be discovered through interaction with a quark, the colour (not the normal visual colour but the specifically quantum-chromodynamical property given the whimsical name 'colour') can not. There is no interaction that reveals quark colour, and so this property is unobservable in principle, where it is a principle of science, not, philosophy. No amount of indirectness can sanction a claim to observe the colour of a quark.

The scientific account will also reveal the theoretical influence on an observation. Consulting science on the matter of observability will show exactly which theories are required to describe the physical indirectness of an observation and to give meaning to what is seen. This allows an assessment of the reliability of the theoretical support as well as its independence from the theories the observation is being used to test.

Given the complication of the issue of observability, and the need to consult the science of each case, the central question must be revised to be amenable to degrees of observability and to the specifics of each case. Of a scientific entity or some information in the world, it is not productive to ask simply whether it is observable or not. Better, more useful, to ask for the whole story, namely, how is it observed, or how is the information acquired? With the details explicit, the epistemic status of the information can be evaluated.

Occasionalism

Occasionalism is often thought of primarily as a rather desperate solution to the problem of mind-body interaction. Mind and body, it maintains, do not in fact causally affect each other at all; rather, it is God who causes bodily movements to occur 'on the occasion of' appropriate mental states (for example, volitions), and who causes mental states, such as sensations, on the occasion of the corresponding bodily states (for example, sensory stimulation).

This characterization, while correct so far as it goes, is seriously incomplete. Occasionalists have seen the lack of real causal influence between mind and body as merely a special case of the more general truth that no two created beings ever causally affect each other. The one and only 'true cause' is God, with created beings serving as the occasions for his causal and creative activity, but never as causes in their own right. (The one possible exception to this is that created agents may themselves bring about their own acts of will; this is necessary if they are to be in any sense free agents.) Occasionalism has always been held primarily for religious reasons, in order to give God the honour due to him as the Lord and ruler of the universe. It has never, however, been a majority view among philosophical theists.

1 Medieval occasionalism

The first thinker clearly to articulate an occasionalist position was the Muslim theologian al-Ghazali. He wrote in defence of orthodox Islam against the philosophers al-Farabi (§2) and Ibn Sina (§5), both of whom propounded emanationist systems based on a combination of Aristotelianism and Neoplatonism (see Creation and conservation, religious doctrine of §3; Aristotelianism in Islamic philosophy §2; Neoplatonism in Islamic philosophy §§2-3). One of al-Ghazali's fundamental objections to the emanationist scheme was that it was necessitarian and denied God the freedom due to him as creator and as the author of miracles. (For al-Ghazali, as for other orthodox Sunnis, human freedom was not a major concern.) Over against this, he affirmed the teachings of orthodox Ash'arite theology, according to which all natural beings are completely inert and the true and sole agent in nature is God (see Ash'ariyya and Mu'tazila). Thus, there is no necessity in nature itself which could constrain or limit God's omnipotent will. Unlike the Ash'arites, however, al-Ghazali presents a philosophical argument for this position. The only form of necessity he recognizes is logical necessity, and he has little difficulty in showing that causes do not logically necessitate their effects. The relation between what we take to be causes and effects is merely one of correlation and is purely contingent; the one real, productive cause of all things is God. In addition to this philosophical argument based on a critique of causality, al-Ghazali appeals directly to the theological dogma of God's absolute omnipotence. Indeed, al-Ghazali's vision of God is such that God is virtually the only true existent: 'There is no other being *with* Him, for Him to be greater than it…. [N]one has being save through His Face - so that His Face alone is' (quoted in Fakhry 1958: 72).

Al-Ghazali's rejection of philosophy was disputed by Ibn Rushd, but his views became widely accepted throughout Sunni Islam. His occasionalism was sharply criticized and rejected by both Maimonides (§4) and Aquinas, and never enjoyed wide support during the Christian Middle Ages. It was, however, embraced by the late medieval Ockhamist philosophers Pierre d'Ailly and Gabriel Biel.

2 Early modern occasionalism

Occasionalism in modern philosophy took its 'occasion' from the problems over causality that arose in Descartes' philosophy (see Descartes, R. §§8, 11, 13). (Not only the problem of mind-body interaction, however; causal interaction among bodies was also problematic for Descartes.) Descartes himself had tendencies towards occasionalism, and this view was adopted by the Cartesian philosophers Louis de La Forge and Géraud de Cordemoy. Arnold Geulincx may have been the first to state an important principle that is also found, in modified form, as a premise in arguments concerning causation given by Malebranche and Hume. The principle states that something cannot be done unless there is knowledge of how it is done; more specifically, people do not do what they do not know how to do. This quickly disposes of the contention that the mind causes bodily movements; in order for the mind to do this, we should have to know how to control the physiological processes involved in making such movements - the firing of neurons, for instance. Clearly, however, we do not know this. The principle also excludes causal efficacy for corporeal bodies, since these bodies obviously lack knowledge of how their

supposed effects are produced.

Nicolas Malebranche (§4) was clearly the most significant of the modern occasionalists. Basing his argument on the supposed impossibility of mind-body interaction, he writes that 'There is no real relation between one body and another, between one mind and another. In a word, no created thing can act upon another by an activity which is its own' (1688: 4.11). He argues, like Geulincx, that in order for our minds to be able to move our bodies we should have to understand, in full anatomical detail, how this is done. He also argues that God's causality pre-empts, as it were, any possible causality among creatures. No creature can exist unless God, by 'continuous creation', wills that it should exist. But in willing that a chair (for example) should exist, God must will that it exist in some particular place, in some particular state of motion or rest, and so on. Clearly, no created power (assuming there to be such) can cause the chair to be at rest or in motion unless God wills that it be so. But if God does will the chair to move, then necessarily it moves; there is nothing left to be done by any created agent. Thus, 'God communicates His power to created beings only because He has made their modifications the occasional causes… which determine the activity of His volitions in consequence of the general laws which He has prescribed to Himself' (1688: 7.10).

Occasionalism did not persist for long as a widely accepted view. But the influence of Malebranche was considerable, and is still felt today through Hume, many of whose sceptical arguments concerning causation derive from Malebranche.

3 The case for occasionalism

Is occasionalism simply a historical curiosity, or does it have the potential to become a viable position for present-day theists? Leaving aside Geulincx's far-from-evident principle, there are two principal arguments for occasionalism, based respectively on the critique of natural causality and on the pre-emptive causality of God. The argument from the critique of natural causality proceeds as we have already seen in al-Ghazali and Malebranche. Various criticisms are employed (many familiar to us through Hume) to argue that causality as we experience it in nature is not the necessary, genuinely productive relationship that we ordinarily take it to be. Natural causation having thus been disposed of, God is invoked as the 'true cause' for whose efficacious acts the various states of created beings are mere occasions. This argument, however, is dialectically weak. The occasionalist begins (as we all must) from our ordinary intuitions about causality developed through our ordinary, everyday causal interactions with the world. These intuitions are then undermined through the critique of causality. But then the occasionalist invokes those very same intuitions in order to point to God as the truly efficacious and productive cause of all that occurs; causation by God, however, is not subjected to the kind of critical analysis that has been applied to natural causation. Clearly, this procedure is inconsistent. If the critique of causality is as effective as occasionalists think, then (as Hume rightly saw) divine causation is, if anything, worse off than natural causation in consequence.

In view of this, the main burden of support for occasionalism needs to be borne by the argument for the pre-emptive causality of God, also employed by both al-Ghazali and Malebranche. (The argument of Malebranche based on continuous creation is a special case of this.) Classical theists are in agreement that God's causal activity must be seen as universal and pervasive throughout the created world. To suppose that there is some part of created reality in which God's activity is not involved is just to make that part of the creation independent of God, which detracts from divine dignity. Any attempt to circumvent this problem by designating different aspects of causation which pertain respectively to God and to creatures runs up against the complaint that the aspect assigned to creatures is removed from the sphere of God's activity, thus diminishing the honour due to God. Medieval Aristotelians tried to meet this challenge by the theory of dual causation, which claims to give full value both to the divine 'first cause' and to creaturely 'second causes'. This theory was spelled out in their doctrines of divine conservation and divine concurrence with creaturely action, but no detailed consensus was arrived at (see Creation and conservation, religious doctrine of §5). Contemporary philosophical theology has barely begun to address the issue, so it could fairly be urged that on this point occasionalism presents theistic philosophy with a challenge it has not yet met.

4 Occasionalism and immaterialism

Whether this argument provides effective support for occasionalism depends on whether occasionalism is itself a tenable view. It can be argued on both epistemological and metaphysical grounds that the material substance

posited by occasionalists is redundant and should be eliminated, leading to a Berkeleyan immaterialism (see Berkeley, G. §§3, 6-7). Epistemologically, occasionalism holds that material substances make no causal contribution towards our perceptions of objects. Occasionalists hold, to be sure, that light waves (for example) travel from observed bodies to our eyes, that nerve impulses connect the eyes with the brain, and that consequent to this we experience visual images. But there is no real causal connection between any two of these stages; in particular, the visual images are not produced by the brain (or even by the immaterial mind), but rather by God 'on the occasion' of the brain's being in an appropriate state. This means, however, that we have no direct evidence for the existence of the supposed intermediate stages in the process, and it is hard to avoid Berkeley's conclusion that it would be simpler for God to omit them.

A similar conclusion can be reached through metaphysical considerations. Occasionalism holds that created substances make no active causal contribution to subsequent states of the world. But then the occasionalist is faced with the question of whether created substances are endowed with causal powers at all. If they are, then God must somehow intervene to prevent the powers from being exercised - and indeed, the provision to created things of powers that are never exercised and are not intended by God to be exercised would seem highly unreasonable. So the occasionalist must deny that created beings possess causal powers. But what, if anything, might created substances consist in, if they lack such powers entirely?

Apparently the occasionalist answer is that while created substances lack active powers they do possess some passive powers; hence al-Ghazali's view of material beings as inert, and Malebranche's willingness to attribute movability and impenetrability (but not active power) to material objects. So as Freddoso suggests, 'God would supply all the active causal power in nature, while material substances would receive and channel God's causal influence as patients' (1988: 111). The difficulty with this is that the active/passive distinction, as we make it, cannot give occasionalism what it needs here. We do have some grip on the difference between an object's acting on another or being acted upon by another. (In many cases this would coincide with the direction of energy transfer.) But the very same molecular structure which makes a billiard ball impenetrable by another billiard ball also enables it, under appropriate conditions, to propel the other billiard ball in a desired direction. The active/passive distinction just does not cut deep enough to play the role it is cast in by occasionalism. But if material substances have neither active nor passive powers, then it is difficult to see the point of their existing - indeed, it is difficult to see what could be meant by claiming that they exist.

The correct conclusion would seem to be that the logic of occasionalism leads to Berkeleyan immaterialism, and that it is in this form, if any, that it may be able to survive as a viable contemporary option. A more attractive option, though slightly more remote from classical occasionalism, can perhaps be found in certain anti-realist interpretations of natural science (see Scientific realism and antirealism). Though diverging from the letter of both occasionalism and Berkeleyanism, these anti-realist views are akin to them in spirit in their desire to uphold science as an empirical enterprise while avoiding the mechanistic materialism which threatens on a realistic interpretation of scientific theories.

Ogyū Sorai (1666-1728)

Ogyū Sorai (1666-1728) was one of the greatest, most erudite and most Sinocentric kogaku, *or 'Ancient Learning', philosophers of Tokugawa Japan. Sorai's call for a return to the most ancient philosophical classics of the Chinese tradition, the Six Classics, voiced the logical conclusion of* kogaku *tendencies. However, Sorai's ideas also inspired* kokugaku, *or 'National Learning', a literary movement advocating a return to the ancient writings of Japan which most purely expressed the Japanese soul prior to its distortion by Chinese philosophy.*

Sorai was born in Edo (now Tokyo), the shogun's capital. From 1679-90 Sorai's father, a *samurai*-physician who served the shogunate, was exiled to rural Kazusa (now in Chiba Prefecture) for reasons which are still unclear. In exile, Sorai's father supervised his son's study of the neo-Confucianism of Zhu Xi, a post-Buddhist, metaphysical form of ancient Confucianism (see Neo-Confucian philosophy). After returning to Edo, Sorai gained attention for his thorough grasp of Zhu Xi's teachings. From 1696 to 1709 he served Yanagisawa Yoshiyasu, grand chamberlain to the Shogun Tsunayoshi (1646-1709), as a scholar. Sorai's ideas informed the decision of Tsunayoshi's government in the 1703 'forty-seven *rōnin*' incident. He argued that the *rōnin* were praiseworthy for fulfilling a private morality, that of duty to their lord, but they also had broken public law by assassinating their lord's enemy, one of the shogun's officials. Rather than humiliate them with inflicted punishment, Sorai advised that the *rōnin* be allowed to commit ritual suicide (see Bushi philosophy §3).

After Tsunayoshi's death in 1709, Sorai became a private scholar. His first publication, a Sino-Japanese dictionary entitled *Yakubun sentei (Expedients for Translating Chinese)*, earned him modest fame in 1711. His next work, the *Ken'en zuihitsu (Reed Garden Miscellany)*, published in 1714, attacked the *kogaku* ideas of Itō Jinsai's *Gomō jigi (The Meanings of Terms in the Analects and the Mengzi)* from a neo-Confucian perspective. Sorai's attacks on Itō Jinsai are odd because earlier Sorai had written him expressing admiration for his *Gomō jigi*. Itō Jinsai never replied, leading to speculation that Sorai wrote the *Ken'en zuihitsu* out of resentment (see Itō Jinsai).

By 1717, Sorai had rejected neo-Confucianism in favour of his own brand of *kogaku* (ancient learning) thought. His masterworks, the *Bendō (Discerning the Meaning of the Way)* and *Bemmei (Discerning the Meanings of Philosophical Terms)*, called for a revival of the ancient Chinese philosophy of the Six Classics. They also attacked both Itō Jinsai's revival of the ancient teachings of Confucius and Zhu Xi's neo-Confucianism for indulging in fanciful subjectivism rather than objective study of ancient philosophical language (see Zhu Xi).

Sorai boasted that his philosophy would revive the Way of the ancient sage-kings (see Confucian philosophy, Chinese). That Way embodied the foundations of civilization, including the rites, music, penal laws and institutions of government. In Sorai's view, the sages earned their status because they invented the Way *ex nihilo*. Sorai thus denied the neo-Confucian claim that the Way existed both in the natural world and in human nature. He believed that there remained only one task for humanity, to follow the ancient Way reverently: neither rulers nor philosophers were to tamper with or deviate from it.

Unlike Zhu Xi, who claimed that sagehood was attainable via investigating things, Sorai alleged that it was impossible for men to become sages. While neo-Confucians insisted that human nature was universally good, Sorai denied that there was any moral value inherent in it. Rather, people were just born with various capacities and talents which could be realized by faithfully following the Way of the sages. When everyone perfected their talents, stability would reign.

While Confucius taught that *jin* (*ren* in Chinese), or humaneness, was a virtue that everyone should embody (see Confucian philosophy, Chinese §5), Sorai interpreted *jin* as the virtue of the great sages which enabled them to provide stability for the world through their Way. Religiously, Sorai insisted that people believe without question in ghosts and spirits, because the ancient sages made such belief part of their Way. Neo-Confucians, however, interpreted ghosts and spirits as the activities of *yin* and *yang*, thus defusing many superstitions about them (see Yin-yang).

During his final years, Sorai provided the Shogun Yoshimune (1684-1751) with solutions for the social and economic ills plaguing the state. His *Taiheisaku (Plan for an Age of Great Peace)* and *Seidan (Discourses on Political Economy)* advised that urban-based *samurai* be relocated in rural areas away from the vices of the

pleasure quarters. Sorai thought that the shogunate could thus provide for stability by creating, like the ancient sages, institutions which would rightly order human and natural resources.

Oken, Lorenz (1779-1851)

In the early nineteenth century, Oken was one of several German scientists who developed views about the metaphysical presuppositions of science, promoted by Kant and especially by Schelling in order to forge links between their scientific investigations and the prevailing Romantic style of thought. Oken's particular concern was with biology, where he introduced bold taxonomic principles drawing on analogies with mathematical polarities and with our sensory and emotional capacities.

Lorenz Oken, or Okenfuss, was born in Bolsbach, in the Baden region of southern Germany, on 1 August 1779. His academic talents were recognized early, the local pastor and a neighbouring Franciscan Gymnasium providing the foundations of a classical education. Before graduating in 1804 from Freiburg University with a medical degree, he had become an enthusiastic supporter of the metaphysical speculations associated with *Naturphilosophie*, a movement endorsed by the early German Romantic thinkers which sought to uncover the general presuppositions of science, and had published an outline of his intended contributions (see Naturphilosophie). In 1807 he was called on Goethe's recommendation to a chair of medicine at Jena University. His *Lehrbuch des Systems der Naturphilosophie (Textbook of Systematic Philosophy of Nature)* was published shortly after his arrival. He remained at Jena, becoming Professor of Philosophy in 1812, but was dismissed in 1819 following his allegedly subversive political activities as editor of *Isis*, a periodical he founded in 1817 with the aim of providing comprehensive information about scientific and other matters to the general reader. The periodical was largely written byOken himself and it rapidly became widely read, partly for the outspoken liberal politics it promoted. He subsequently held teaching posts in medicine and physiology at several universities, and was instrumental in founding the influential *Gesellschaft Deutscher Naturforscher und Ärzte* (German Society for Scientists and Doctors) in 1822. He ended his career as Rector of Zürich University and died in Zürich on 11 August 1851.

Like other post-Kantian thinkers, Oken believed that the structures in terms of which we understand the natural world are supplied, not by that world, but by the mind. Kant himself had initiated investigations of the metaphysical foundations of science which were intended to reveal these structures, and Oken's contemporaries, such as Hegel and Schelling, responded with their own versions of a philosophy of nature (see Hegel, G.W. §7; Schelling, F.W. §1). In Oken's writings we find little of the logical analysis that these philosophers employed in describing these mental structures; instead, his abstract and generalized language conveyed in a philosophical idiom the Romantic conviction that imagination and feeling should play their part in scientific understanding. Thus, he took the applicability of mathematics to nature as a foundation for ideas about the spiritual and material, the eternal and the temporal, which also found expression in contemporary German Romantic poetry and art. For if nature is constructed by the self, though in opposition to the self, then as a whole it corresponds to mathematical infinity, because the self constructs it as unlimited in space, time and scope. And the origin of nature (conceptually, if not historically) corresponds to zero because the self constructs nature as originating from nothing, albeit with infinite potential. These constructs of an infinite nature and a primeval nothing are in polar opposition to each other, and the interaction between them generates our constructions and understandings of nature, just as the interaction between our conceptions of zero and infinity generates our constructions and understandings of natural numbers. In common with philosophers writing in the Romantic idiom of irony, contradiction and unrestrained feeling, Oken subjected language to enormous pressure. The resulting syntactical intensity mystified his readers but it was integral to the fervour of his thought, including his thought about nature.

In the physical sciences, his thinking was close to that of Schelling. Indeed, the two men were in contact during the first decade of the nineteenth century, when Oken was developing his philosophy of nature. Both understood optical, electrical and magnetic phenomena in terms of polarities of light and darkness, attraction and repulsion, these polarities being manifestations of an abstract dialectic of productivity and product. Oken's tone when writing of these matters was one of enthusiastic endorsement rather than critical consideration, and his aphoristic style encouraged him to affirm rather than defend his conclusions. He did not, therefore, provide the elucidation of the difficulties of this philosophy that his contemporaries might have sought or that modern readers might require.

The biological and medical sciences were, he found, fruitful fields in which to apply the concepts and analogies

suggested by his philosophy. They were, too, the sciences in which his expertise was recognized, for he was renowned as a meticulous descriptive anatomist. But the conventionality of his practical science stands in sharp contrast to the boldness of his theoretical speculations. So, for example, in taxonomy he used the idea of a single series of increasingly complex organisms, beginning with primal organisms, or *'Ur-thiere'*, and ending with human beings. Just as the comparable sequence of natural numbers displays patterns which are repeated within segments of the sequence, so Oken sought repeating patterns within his taxonomic series. In his earliest writings he had used the language of sensory and emotional capacities, often metaphorically, to describe these patterns, and he found imaginative ways of providing evidence of their applicability. However, if such patterns were not produced by perceptions of nature but by conceptions of our minds, it is not surprising that he was sometimes casual in confirming the details they implied.

Oken has a place in the history of biology and medicine for his experimental contributions to comparative anatomy, and for some of his taxonomic ideas which are said to anticipate certain modern views. His aim of bringing a Romantic style of thinking into his science led him to explore *Naturphilosophie*, and, in the history of philosophy, his significance is bound up with that of the distinctive coupling of speculative science with idealistic metaphysics. Certainly, Oken's philosophy served a need among his contemporaries, but it was his pedagogic and investigative skills, rather than his philosophical acumen, that earned their admiration.

Olivecrona, Karl (1897-1980)

Olivecrona was a Swedish jurist of the 'realist' school, and from 1933 Professor of Procedural Law in the University of Lund. He regards law as a body of 'independent imperatives' effective in bringing about certain patterns of behaviour in society. The reality of law is psychological and behavioural, not dependent on some metaphysical world of norms.

Olivecrona's theory is non-voluntarist: there is no individual or group 'lawmaker' whose will constitutes law. Legal rules are not strictly imperatives. Yet in setting patterns of behaviour they have an expressive and emotive function and are regarded by the addressees as if they were imperatives.

Many independent imperatives have a performative form: they purport to create ideal power-relations, rights, duties and the like, and only indirectly to command action or abstention in a physical sense. Such performatives prompt beliefs in valid law and rights, but these beliefs do not (cannot) refer to any fact. Yet they have social functions. They direct human conduct, facilitate concise law-making, and even convey some vague information, for example, that the 'owner' of an estate in the usual course of things has a kind of control over it. The most important function of criminal law is to promote the conviction that crime leads to punishment (see Legal concepts §4).

Olivecrona in his later work pursued the history of ideas about rights and related concepts. In this, he contributed to understanding the crucial role of the idea of *suum* in the natural law theories of, among others, Grotius and Pufendorf. This idea is at the heart of ideas both of property and of personal rights to non-interference by others.

Olivecrona was a disciple of Axel Hägerström (§4), according to whom all knowledge concerns reality in time and space and the concept of value is inconsistent with reality; hence 'binding' law is an illusion. He has been grouped with Alf Ross and Vilhelm Lundstedt as a 'Scandinavian realist' (see Legal realism §1), their 'realism' descending from Hägerström's anti-idealist materialism. Their work wrestles with significant problems concerning normative concepts such as 'right' and 'duty'. If these do not have material counterparts, but function in essentially action-guiding ways, what theory of language and of reality properly captures their sense? If philosophy peels off the air of magic and mystery surrounding them, can they continue to guide action effectively?

Olivecrona's work deserves credit for its clarity in posing the fundamental problems of legal philosophy. He gave a precise and comprehensive reconstruction of the conceptual apparatus of law consistent with his anti-metaphysical framework (see Legal positivism §5). Yet such a reconstructionism can be criticized as too remote from the internal point of view of lawyers and inadequate to capture legal reasoning and legal thought in the context of justification (see Legal reasoning and interpretation). If juristic opinions are merely emotive and expressive, how can they be discussed intersubjectively? How can lawyers honestly fulfil their beneficial social functions (rightly recognized by Olivecrona) if they regard the 'valid law' as mere illusion?

Olivi, Peter John (1247/8-98)

Condemned repeatedly by religious authorities, Peter John Olivi is one of scholasticism's most original and colourful figures. Although better known for his involvement in social and political debates within the Franciscan order, Olivi also took up the leading epistemological and metaphysical concerns of his day. His outright scorn for Aristotle and cautious rapport with Augustine combine to produce an exciting, insightful body of philosophical work.

Olivi studied in Paris without becoming a master of theology and spent much of his adult life teaching at various Franciscan houses in southern France. Although he produced a wide-ranging body of work, most of his philosophical views are contained in his question-commentary on the second book of Peter Lombard's *Sentences* (see Lombard, P.) This lengthy treatise takes up a wide range of philosophical problems such as the nature of matter, form, substance, quantity, the soul, causation, motion and the problems of universals and individuation. Although imbued with the Aristotelian terminology and perspectives of his contemporaries, Olivi feels free to reject this influence when it suits him. He characteristically remarks of Aristotle, 'his authority and that of any infidel and idolator is nothing to me - especially as regards matters that belong to the Christian faith or are very near to it' (*Quaestiones in secundum librum Sententiarum* q.16 ad 6).

Many of Olivi's most interesting and influential arguments concern human volition and cognition. His views on these topics are often strikingly similar to those of his Franciscan successors John Duns Scotus and William of Ockham. Olivi opposes any account from which it would follow that our will is constrained in its choices or determined to select one alternative over another. By his standards, human freedom requires that persons be able, at the same time at which they choose one thing, to choose instead its opposite; in other words that 'someone does one thing in such a way that at the same time he could have done the other while ceasing from the first - and vice versa' (*Quaestiones* q.57 ad 4). Olivi thinks that if free will is to be preserved, this counterfactual must hold not just until the moment of decision, but also at the moment of decision itself. To explain this difficult claim - that at the same time at which I did one thing I could have done the other - Olivi invokes the notion of natural priority (*Quaestiones* q.57 ad 10). Even though it seems as if I could not choose to cross the street at the very moment that I choose not to cross the street, I have an ability to choose otherwise which is naturally prior to but temporally simultaneous with the choice that I do make.

Olivi needs to make these subtle conceptual distinctions in order to reject any passivity or determinism on the part of will. In particular he wants to deny that the will is determined to choose in accordance with intellect's counsel. Intellect's role in decision-making is to present to the will various alternatives, presenting them as good in various respects. The will's own freedom, he holds, is a completely sufficient cause for its choosing one of those alternatives over another. Hence 'if one is asked why [a volition] ceases…it is fully sufficient to reply by saying that it was completely and sufficiently able to cease' (*Quaestiones* q.57 ad 5). Olivi claims that demanding any further explanation leads to the destruction of free will.

It is a peculiar feature of Olivi's thought that he sees a close connection between taking the will to be passive (and hence not free) and taking the cognitive powers to be passive. He says that it is the doctrine of the passivity of cognition that 'above all things moves many to believe that our will is totally passive' (*Quaestiones* q.58 ad 14). Olivi doesn't explain why anyone would link these two issues, but his concern on this point leads him to append to his discussion of will an extended attack on the standard medieval Aristotelian theory of human cognition. His central claim is that the human cognitive powers (intellect and senses) are not passive. To maintain this claim, Olivi reverses the usual causal order. We do not cognize in virtue of *receiving* external impressions; rather, our cognitive powers somehow reach out directly to their objects in the world. While Olivi rejects the ancient account in which vision takes place through a physical extromission, he allows what he calls a 'virtual extension' of the cognitive powers to the external world (*Quaestiones* q.26).

Although Olivi discusses the notion of virtual extension at length, it is never quite clear what he has in mind. However, the motivation for this position is clear enough. In part, he wants to reject any sort of passivity on the part of our cognitive powers. Further impetus comes from his claim that 'no body can directly move the soul's sensory powers, and much less the intellectual ones' (*Quodlibeta* I.4). In place of a direct causal connection, Olivi

postulates an obscurely explained ‘natural link’ (*colligantia naturalis*) between mind and body (*Quaestiones* q.111). In the standard scholastic account, on the other hand, external objects produce forms (known as sensible and intelligible species) in our cognitive faculties. Olivi denies not only that these species are produced by external objects, but also that such species occur at all: there is no internal representation of objects in the external world beyond the act of cognition itself. This view became common in the fourteenth century (in the works of Ockham, for example), but Olivi seems to have been the first to hold it. His most interesting arguments are epistemological. If there were such species, he says, we ‘would be diverted from seeing the object rather than led toward seeing it’ (*Quaestiones* q.74). On this basis he raises sceptical problems concerning our knowledge of the external world. His theory of virtual extension, in contrast, allows a direct realist account of cognition.

Olivi’s rejection of sensible and intelligible species was condemned by the Franciscan authorities, along with many of his other views. It seems clear that these philosophical claims drew ecclesiastical condemnation primarily because of his involvement in the controversial Franciscan spiritual movement. In any case, all of Olivi’s writings were twice condemned and ordered to be burned. For this reason, at least, his work received less philosophical attention than it deserves. Enough of his writings have survived, however, so that this neglect need not persist.

Oman, John Wood (1860-1939)

A central theme of John Wood Oman's writings is the possibility and actuality of knowledge that is not gained through science. He rejects as too simplistic the mechanistic view of the world. His belief in God rests not on the arguments of natural theology, but on the force and content of religious experience. The source of religion is to be found in our sense of the supernatural, from which stems also our moral dependence on God.

Born in the Orkney Islands in 1860, John Wood Oman was educated at the universities of Edinburgh and Heidelberg and served as a pastor in northern England for seventeen years. He then taught for a further twenty-eight years at the seminary of the English Presbyterian Church at Westminster College, Cambridge. He translated Friedrich Schleiermacher's *Lectures to Cultured Despisers of Religion* into English, and his emphasis on the centrality of religious experience was influenced by Schleiermacher's theology (see Schleiermacher, F. §7). He died in 1939.

Oman held religion to be an actual experience of an actual environment. It involves awareness of the holy, a direct sense or feeling of the supernatural. It also involves awareness of the sacred and a valuation of the supernatural as possessing absolute worth (see Religious experience §1). The distinction between natural and supernatural is coextensive with the distinction between relative value and absolute value. None the less, Oman held, religion's core is not this sense or its accompanying valuation, but their object; its emphasis is not on experiences or feelings, but on what elicits them.

In *The Natural and the Supernatural* (1931), Oman finds the source of religion in a sense of the supernatural. The supernatural, he says, is a kind of environment with its own sanctions. Experience of this environment provides humans with a degree of transcendence of their natural environment. Contact with any environment includes perception of meaning, and perception of meaning typically involves interpretation as well as recognition. Hence there are differences in how the actual environment is conceived, and consequent differences in how it is experienced.

In primitive religion, the supernatural is conceived animistically. In polytheism, it is thought of as distinct divinities each ruling over a part of nature. In cosmic pantheism, it is viewed as an organic whole with integrally related parts. In idealistic pantheism, it is thought of as a spiritual whole without matter. Thus contacting animistic spirits, placating nature's rulers, finding unity with the cosmos, and escaping illusion, are seen as means of salvation in these religions. Different notions of salvation correlate with diverse conceptions of the supernatural.

In monotheism, the supernatural is conceived as a personal God. Priestly, legalistic religions divide the world into the secular and the sacred; prophetic religions find the supernatural through the natural. Those who follow priestly religions seek the supernatural through ceremonies, and those who embrace prophetic religions see their life as worship and their duties as God's commands. For priestly religions, daily awareness of one's mundane life contains a sense of abiding purpose, and the sense of the supernatural includes an awareness of something of unconditional worth that lays an absolute claim upon our devotion and obedience. Refusal to worship and obey divides one from the supernatural environment in which one's true hope lies.

For all of its diversity, Oman contends, religion has two main branches: 'pantheism and absorption into the One…monotheism and victory over the many' (1931: 407). The former focuses on escaping from the world, the latter endeavours to create a better world. Oman views prophetic monotheism, as manifested in the Old Testament prophets and in the teachings of Jesus, as the highest religion.

In *Grace and Personality* (1919), Oman discusses an issue fundamental to prophetic religion:

> The essential quality of a moral person is moral independence and an ideal person would be of absolute moral independence. But the essential quality of a religious person is to depend on God; and he must be as absolutely dependent as a moral person must be absolutely independent.
>
> (1919: 58)

For prophetic religions, every good is given by divine courtesy and none is due to human effort. From the moral point of view, nothing that is morally good can be deterministically produced. Oman suggests that grace involves

God's giving us sufficient insight to see that what God wills is coextensive with what realizes our humanity; grace thus is not coercive but persuasive. Morality is not an arbitrary law, externally imposed, but a pattern for realizing our nature as persons.

Oman emphasized the importance of religious and moral experience in theology and philosophy of religion while also insisting on consistency and coherence. He was interested in religious traditions other than his own, and willing to learn from them. He did not suppose that this required that he reject his own tradition, think all experience equal, embrace relativism, or abandon efforts at rational assessments of religious doctrines.

Omnipotence

Traditional theism understands God to be the greatest being possible. According to the traditional conception, God possesses certain great-making properties or perfections, including necessary existence, omniscience, perfect goodness, and omnipotence. Philosophical reflection upon the notion of omnipotence raises many puzzles and apparent paradoxes. Could an omnipotent agent create a stone so massive that that agent could not move it? It might seem that however this question is answered, it turns out that, paradoxically, an omnipotent agent is not truly all-powerful. Could such an agent have the power to create or overturn necessary truths of logic and mathematics? Could an agent of this kind bring about or alter the past? Is the notion of an omnipotent agent other than God an intelligible one? Could two omnipotent agents exist at the same time? If there are states of affairs which an omnipotent agent is powerless to bring about, then how is the notion of omnipotence to be intelligibly defined? Yet if the notion of omnipotence is unintelligible, then traditional theism must be false. Another obstacle to traditional theism arises if it is impossible for God to be both perfectly good, and omnipotent. If an omnipotent God is powerless to do evil, then how can God be omnipotent?

1 What omnipotence means

The intelligibility of the divine attributes, considered individually and in combination, is a central concern among philosophers of religion. Among the attributes of the God of traditional theism is omnipotence. Some philosophers have tried to understand omnipotence in terms of the power to perform some suitably comprehensive set of tasks. Examples of tasks are to create a stone too massive for oneself to lift, to do evil, or to make oneself non-omnipotent. Experience has proved, however, that such an approach to the analysis of omnipotence is fruitless. More promising is the effort of some philosophers (such as Rosenkrantz and Hoffman 1980a, Flint and Freddoso 1983, and Wierenga 1989) to analyse omnipotence in terms of the power to bring about a suitably defined set of states of affairs (where a state of affairs is a propositional entity, which either obtains or fails to obtain).

Two senses of 'omnipotence' come to mind. First, there is the notion of having it within one's power to bring about any state of affairs whatsoever, including impossible and necessary states of affairs. Descartes, in the *Meditations* (1641), appears to have had a notion close to this one. But, as Aquinas in his *Summa theologiae* (1266-73) and Maimonides in his *Guide for the Perplexed* (*c*.1190) recognized, it is not possible for an agent to bring about an impossible state of affairs (for example, there being a colourless red object), since if it were, it would be possible for an impossible state of affairs to obtain, which is a manifest contradiction. Nor is it possible for an agent to bring about a necessary state of affairs (for example, any red object's being coloured). If it is possible for an agent, *a*, to bring about a necessary state of affairs, *s*, then possibly, (1) *a* brings about *s*, and (2) if *a* had not acted, then *s* would not have obtained. But a necessary state of affairs obtains whether or not anyone acts, so (2) is false. Therefore, it is not possible for an agent to bring about a necessary state of affairs. The first sense of omnipotence is consequently unintelligible.

A second sense of 'omnipotence' is that of maximal power. In this sense, the overall power of an omnipotent being could not be exceeded by any being. It does not follow that a being with maximal power can bring about every state of affairs, since doing so is impossible. Nor does it follow that a being with maximal power can bring about everything that any other being can bring about. From the fact that *a* can bring about *s*, and *b* cannot, it does not follow that *a* is overall more powerful than *b*, for it might be that *b* can bring about some thing or things that *a* cannot. This is the only sense of omnipotence that may be coherent. Thus, if a putative analysis of the concept of omnipotence is offered in defence of its intelligibility, then it should be an attempt to analyse the concept of maximal power.

Power is not the same thing as ability. Power is ability plus opportunity. A being who had maximal ability but was prevented by circumstances from exercising it would not be omnipotent. Necessarily, nothing prevents an omnipotent being from exercising its powers when it wills to do so.

Some have thought that there could be two (or more) omnipotent agents, a_1 and a_2, at the same time, t. If this were possible, then it could happen that at t, a_1 strives to move a button (while remaining omnipotent), and at t, a_2 strives to keep that button still (while remaining omnipotent). In a case of this kind, the button would be unaffected

(as to its motion or rest) by either one of them. Thus, in such a case, a_1 would at *t* lack the power to move the button, and a_2 would at *t* lack the power to keep the button still. Since it is absurd to suppose that an omnipotent being lacks the power to move a button or the power to keep it still, neither a_1 nor a_2 is omnipotent. Hence, there could not be two omnipotent beings at the same time.

Could there be a contingently omnipotent being? This seems possible on first thought, but the following argument seems to show the opposite. A being cannot have any perfection unless it has every perfection. This, together with the assumptions that a contingently omnipotent being has a perfection, and that an essentially omnipotent being has a perfection (namely essential omnipotence) which a contingently omnipotent being lacks, implies that contingent omnipotence is impossible.

In addition, assuming that traditional theism is true, God has necessary existence and is essentially omnipotent. Since there could not be more than one omnipotent being, it follows that there could not be a contingently omnipotent being (see Necessary being).

However, the first argument against the possibility of contingent omnipotence is incorrect. For example, a perfect triangle need not have the perfections of omniscience or omnipotence. Thus, it is false that a being cannot have a perfection unless it has every perfection.

The second argument against the possibility of contingent omnipotence presupposes traditional theism. But in analysing omnipotence, it is preferable to remain neutral about whether theism is true or false. In that case, omnipotence will not be assumed to be attributable only to the God of traditional theism or only to an essentially omnipotent being.

2 The paradox of the stone

One challenge to the coherence of the notion of omnipotence is based on the so-called paradox or riddle of the stone. Can an omnipotent agent, *a*, bring it about that there is a stone of some mass, *m*, which *a* cannot move? If the answer is ‘yes’, then there is a state of affairs that *a* cannot bring about, namely (i) that a stone of mass *m* moves. On the other hand, if the answer is ‘no’, then there is a different state of affairs that *a* cannot bring about, namely (ii) that there is a stone of mass *m*, which *a* cannot move. Thus, it might appear that omnipotence is paradoxical. But the appearance of paradox can be overcome if either (i) or (ii) is impossible, for, as has been seen, an omnipotent agent need not be able to bring about an impossible state of affairs. If, on the other hand, both (i) and (ii) are possible, then it is possible for some omnipotent agent to bring it about that both (i) and (ii) obtain, though at different times, and so there is a second solution to the paradox.

The first solution comes into play when there is an *essentially* omnipotent agent, a_1. The state of affairs of a_1’s being not omnipotent is impossible. Therefore, a_1 cannot bring it about that a_1 is not omnipotent. Since, necessarily, an omnipotent agent can move any stone, no matter how massive, state of affairs (ii) is impossible.

The second solution presupposes the only other alternative: that there is a *contingently* omnipotent agent, a_2. In this case, a_2’s being non-omnipotent is a possible state of affairs; and presumably, it *is* possible for a_2 to bring it about that a_2 is non-omnipotent. So a_2 can create and move a stone of mass *m* when omnipotent, and *then* bring it about that a_2 is not omnipotent and is unable to move that stone of mass *m*. Thus, a_2 is able to bring about both (i) and (ii), but only if they obtain at different times.

3 Things that an omnipotent agent is powerless to do

At this point, it might be thought that an analysis of omnipotence could be simply stated as the power to bring it about that any contingent state of affairs obtains. However, the following contingent states of affairs show that this simple analysis fails:

(a) A stone rolled.
(b) A stone rolls at *t* (where *t* is a past time).
(c) Socrates walks for the first time.
(d) The Nile floods an odd number of times less than four.

(e) A ball rolls and no omnipotent agent ever exists.
(f) Jones freely decides to walk.

(a) is a past state of affairs. Since it is impossible for any agent to have power over the past (this is the so-called ‘necessity of the past’), no agent, not even an omnipotent one, can bring about (a). Similarly, although (b) can be brought about prior to *t*, the necessity of the past implies that even an omnipotent agent cannot bring about (b) after *t*. In the case of (c), prior to Socrates’ first walk, an omnipotent agent can bring about (c). But once Socrates has walked, even an omnipotent agent cannot bring about (c). With respect to (d), before the Nile’s third flooding, an omnipotent agent can bring about (d), whereas after the Nile’s third flooding, even an omnipotent agent is powerless to bring about (d). (e) presents a special problem. While it is clear that (e) could not be brought about by an omnipotent agent, some philosophers (such as Hoffman and Rosenkrantz 1988) argue that it is possible for a non-omnipotent agent to bring about (e) by rolling a ball when, in fact, no omnipotent agent ever exists. (Recall that a maximally powerful being need not be able to bring about every state of affairs that any other being can.) Finally, an omnipotent agent other than Jones cannot bring about (f) if the libertarian theory of free will is correct, but apparently a non-omnipotent agent - namely Jones - can bring about (f).

Thus, an adequate analysis of omnipotence should not require an omnipotent agent to have the power to bring about (a), (b), (c), (d), (e) or (f), assuming in the case of (f) that libertarianism is correct. Given the seemingly wide disparity among contingent states of affairs (a)-(f), it might be conjectured that there is no analysis of omnipotence that can deal adequately with all of them while capturing the intuitive scope of power involved in omnipotence. Yet the following observations set the stage for just such an analysis.

For an adequate analysis of omnipotence, identifying some distinctive features of (a)-(f) might enable one to state an analysis of this kind. First, as (a) is not possibly brought about by any agent, an omnipotent agent should not be required to have the power to bring about a state of affairs unless it is possible that some agent brings about that state of affairs. Second, although (b) and (c) are possibly brought about by some agent, they are not repeatable - in other words, it is not possible that they obtain, then fail to obtain, and then obtain once more. (Note that the conditions that do not require an omnipotent agent to be able to bring about (a) and (b) also do not require that agent to be able to bring about impossible or necessary states of affairs.) Third, while (d) is repeatable, it is not unrestrictedly repeatable - it cannot obtain, then fail to obtain, then obtain again, and so forth throughout all of time. Fourth, even if (e) is unrestrictedly repeatable, it is a complex state of affairs, namely a conjunctive state of affairs, whose second conjunct is not repeatable. Reflection on the nature of repeatability and its relation to the power to bring about states of affairs leads to the conclusion that an omnipotent agent ought not to be required to have the power to bring about either a state of affairs which is not unrestrictedly repeatable or a conjunctive state of affairs one of whose conjuncts is not unrestrictedly repeatable. Finally, although (f) is unrestrictedly repeatable, (f) is identifiable with or analysable as a conjunctive state of affairs having three conjuncts, whose second conjunct is not possibly brought about by anyone. The conjunctive state of affairs in question can be informally expressed as follows: (I) Jones decides to walk, and (II) there is no *antecedent* sufficient causal condition of Jones’ deciding to walk, and (III) there is no concurrent sufficient causal condition of Jones’ deciding to walk. Because, as we have explained, it is impossible for an agent to have power over the past, the state of affairs which is the second conjunct of this conjunctive state of affairs is not possibly brought about by anyone. Hence, an omnipotent being should not be required to have the power to bring about a state of affairs which is identifiable with or analysable as a conjunctive state of affairs one of whose conjuncts is not possibly brought about by anyone.

4 An analysis of omnipotence

Based on insights gleaned from the preceding discussion, omnipotence can be analysed in three steps as follows (where ‘ $=_{\mathrm{df.}}$ ’ means ‘is defined as’):

Step 1. The period of time *t* is a sufficient interval for $s =_{\mathrm{df.}} s$ is a state of affairs such that: it is possible that *s* obtains at a time-period which has the duration of *t*.

Step 2. A state of affairs *s* is unrestrictedly repeatable $=_{\mathrm{df.}}$ s is possibly such that:
$(\forall n)(\exists t_1)(\exists t_2)(\exists t_3)\ldots(\exists t_n)(t_1 < t_2 < t_3 < \ldots < t_n$ are periods of time which are *sufficient intervals* for *s*, & *s* obtains at t_1, *s* does not obtain at t_2, *s* obtains at $t_3, \ldots,$ *s* obtains at $t_n \equiv n$ is odd).

In the preceding definition, *n* ranges over all natural numbers, and $t_1, \ldots, t_n$ are non-overlapping. Also, it is assumed for the purposes of this definition that either it is possible that time has no beginning, or it is possible that time has no end.

Step 3. (D1) *x* is omnipotent at *t* $=_{\text{df.}}$ $(\forall s)$ (it is possible for some agent to bring about *s* $\rightarrow$ at *t*, *x* has it within his power to bring about *s*).

In (D1), *x* ranges over agents, and *s* over states of affairs which satisfy the following condition:

(C1) (Ci) *s* is unrestrictedly repeatable, and of the form 'in *n* minutes, *p*', & (*p* is a complex state of affairs $\rightarrow$ each of the components of *p* is unrestrictedly repeatable & possibly brought about by someone), or (Cii) *p* is of the form '*q* forever after', where *q* is a state of affairs which satisfies (Ci).

Two technical explanations concerning (C1) are in order. First, *n* ranges over real numbers, and *p* is not itself equivalent to a state of affairs of the form 'in *n* minutes, *r*', where *n* is not equal to zero. Second, by a *complex* state of affairs is meant a state of affairs which is either constructible out of other states of affairs by use of the logical apparatus of first-order logic enriched with whatever modalities one chooses to employ, or else analysable (in the sense of a philosophical analysis) into a state of affairs which is so constructible. Accordingly, a *component* or *part* of a complex state of affairs *s* is one of those states of affairs out of which *s*, or an analysis of *s*, is constructed.

Happily, (D1) does not require an omnipotent agent to be able to bring about impossible or necessary states of affairs, or states of affairs such as (a)-(f). Moreover, (D1) does not imply that an omnipotent agent lacks any powers which an agent of this kind ought to possess. This is because an agent's bringing about a state of affairs can always be 'cashed out' in terms of that agent's bringing about an unrestrictedly repeatable state of affairs which satisfies the antecedent of the definiens of (D1). In other words, necessarily, for any state of affairs *s*, if an agent *a* brings about *s*, then either *s* is an unrestrictedly repeatable state of affairs which satisfies the antecedent of the definiens of (D1), or if not, then *a* brings about *s* by bringing about *q*, where *q* is an unrestrictedly repeatable state of affairs which satisfies the antecedent of the definiens of (D1). For example, an omnipotent agent can bring about the state of affairs 'that in one minute, Socrates walks for the first time' by bringing about the state of affairs 'that in one minute, Socrates walks', when this walk is Socrates' first. And while the former state of affairs is a non-repeatable one which (D1) does not require an omnipotent agent to be able to bring about, the latter state of affairs is an unrestrictedly repeatable state of affairs which (D1) does require an omnipotent agent to be able to bring about.

5 On the compatibility of God's omnipotence and perfect goodness

Some philosophers have thought that omnipotence is incompatible with certain other attributes. In particular, it has been argued that traditional theism, which posits a necessary, essentially omnipotent, essentially omniscient and essentially perfectly good deity, is faced with this problem. The charge has been that such a deity lacks the power to bring about evil, while non-omnipotent (and morally imperfect) beings such as ourselves possess this power. The exact form of the problem varies depending on what exactly the relation between God and evil is supposed to be. Suppose that if God exists, then this is a best possible world. Then if God exists, there could not be an evil unless it is necessary for some greater good, and any state of affairs containing evil incompatible with there being a maximally good world is impossible. Such a state of affairs could not be brought about by any agent whatsoever. In that case, any evil that any person brings about (moral evil) or that occurs in nature (natural evil) is necessary for some greater good. Assume that God exists and that, for instance, some person, *S*, brings it about that an evil, *e*, exists. Then, given our assumptions, since *S*'s bringing it about that *e* exists is necessary for some greater good, it is compatible with God's perfect goodness that God brings it about that *S* brings it about that *e* exists. On the other hand, if God exists and some or all evil is metaphysically incompatible with this being a maximally good world, then neither God nor anybody else has the power to bring about that evil. The main idea here is that if God's nature places moral restrictions on the nature of the universe and on what God can bring about, then it also places parallel restrictions on what any other agents can bring about. So, for example, if there being suffering in the universe is necessary for this being a maximally good world, then God cannot create a (maximally good) world without the presence of suffering of the appropriate sort (see Evil, problem of).

Other theists, for example, Alvin Plantinga, do not hold that God's existence implies the existence of a maximally

good world, but do hold that God seeks to create as good a world as God can (see Plantinga 1974). They allow that there may be evil that is unnecessary for any greater good that outweighs it. An evil of this sort involves free decisions of agents other than God which God does not prevent but which these other agents can prevent. Plantinga argues that God does no wrong in permitting an evil of this kind because God is powerless to bring about a crucial good - the existence of free human agents - without there being such an evil. Alternatively, it might be argued that God does no wrong in this sort of case because God does not know how to do better, since such knowledge is impossible. However, as an omnipotent God is *not* required to have power over free decisions of agents other than God, it can be seen that on these views, God's omnipotence and perfect goodness can be logically reconciled to the extent indicated along the lines taken above in discussing the view that God's existence requires a maximally good world. Of course, nothing that has been said here decides the issue of how much, if any, evil is compatible with the existence of the traditional God.

Omnipresence

Western Scripture and religious experience find God present everywhere. Western thinkers make sense of this as their concepts of God dictate. Pantheists hold that God's being everywhere is every bit of matter's being a part or an aspect of God. Panentheists say that as God is the soul of the universe, God's being everywhere is his enlivening the whole universe as souls enliven bodies. But most theists reject these views, as most think that if God is perfect, he cannot be, be made of, or be embodied in a flawed and material universe. Most theists think God intrinsically spaceless, that is, able to exist even if no space exists. Still, theists argue that God's knowledge of and power over creation make him present within it without occupying space or being embodied in matter. Some add that God is present in space not just by power and knowledge but in his very being. These try to explain a spaceless God's presence in space by likening it to the presence of a universal attribute like hardness. Hardness is not spread over hard surfaces, occupying them by having parts of itself in parts of them. Each part of a hard surface is hard. So all of hardness is in each part of a hard surface. So too, theists say, God is not spread out over space, filling parts of it with parts of himself. Rather, all of God is wholly present at each point in space and in each spatial thing.

1 Introduction

Western Scripture vividly states that God is present everywhere. The Psalmist asks:

> Where can I go from your Spirit?
>
> Where can I flee from your presence?
>
> If I go up to the heavens, you are there;
>
> If I make my bed in the depths, you are there.
>
> If I rise on the wings of the dawn, if I settle on the far side of the sea,
>
> even there your hand will guide me, your right hand will hold me fast.

(Psalms 139: 7-10)

Theists fill out the concept of God mainly by drawing inferences from God's being perfect (see God, concepts of §§2-6). Such thinking also backs the claim that God is omnipresent: a God from whose presence one could escape would be less perfect than a God inescapable.

If time and space are really one, God is omnipresent in time as in space. But most have thought of omnipresence only in relation to space, so this entry treats only space. We are present in each volume of space which includes us: the space of this room, and also this galaxy. But we are primarily present only in places we fill (I am in the galaxy because my body fills a place which is in the galaxy) and immediately present only to places directly next to our places. So if God is perfectly present to every place, he either fills or is next to each place. If nothing can exclude God, God fills not just places but the things which occupy them.

2 Omnipresence and embodiment

Pantheism is the doctrine that all material things compose or manifest one thing, which is God (see Pantheism). If all matter is part or an aspect of God, then God is wherever any material object is, that is, wherever God has a part or aspect. But the whole of God is not where any one part of God is, and God is not literally everywhere if there are true vacua, though he permeates all space if (say) some part of God is present in each volume of space, however small. Treatments of omnipresence should distinguish its nature (what it is to be omnipresent), cause (what makes God omnipresent) and manner (the kind of presence God has everywhere). For pantheism, then, God's omnipresence (if any) is the way space contains God; it rests on God's having every object as a part or aspect, and God is present as material objects are: parts of God in parts of a location, and the whole of God in the whole. Spinoza (§§2-4) (if a pantheist) is an exception, claiming that though all extension is an attribute of God, and all bodies modes of God, God has no parts or at least is indivisible (*Ethics* I, props 12-13).

For Stoic panentheists, 'God' named the spirit whose body is the cosmos, and also the living cosmos that spirit

enlivens. So Stoics thought that God permeates the cosmos as a soul permeates its body, sustaining the cosmos as soul sustains body. The Stoic world-soul was a fiery material stuff. So Stoics held that the stuff of God occupies space and shares spaces with all other material stuffs, which are not parts of God quite as the cosmos' fiery parts are. The Stoic theory of mixture allowed this, claiming that all ingredients of a mixture are present in each place the mixture occupies. For Stoicism, the cosmos existed amid a surrounding vacuum, and so though omnipresent in the cosmos, God was not literally present in every place. For Stoics, a finite space circumscribes God: the cosmos' dimensions are God's. To Stoics, then, God's omnipresence in the cosmos is the way he enlivens it; it rests on the world's embodying God, and God is in the world as soul in body (see Stoicism §§3-5).

One's account of omnipresence depends largely on whether one holds that:

(UB) the universe is God's body.

Why accept (UB)? If one finds pure physicalism a persuasive metaphysic, (UB) gives God a place within it. It surely is at least easier to understand the claim that God acts if God has some sort of body; this makes his actions more like those of persons we know. The Stoics thought that only material things *can* act. Tertullian agreed, and inferred that God is a body (*Against Praxeas*, ch. 7); the Stoics inferred that God must be not just material but the most perfect material thing, the cosmos (see God, concepts of §3). Swinburne argues that embodiment comes in degrees, and that the way God knows and acts in the universe embodies him in it to some extent. That is one's body, Swinburne reasons, which one can control or move directly as a 'basic action', and about whose states one knows immediately (1993: 104-6). Hartshorne (1964: 200) makes the same case. Sarot (1992) argues that God has emotions which require having a body. Some feminists (for example, McFague 1987: 69-77) argue that its ethical and spiritual consequences favour (UB).

None of this is compelling. Bodiless agency, mental life and feelings are conceivable; recent philosophy of mind helps by stressing the *functional* cores of our concepts of thought, action and emotion (Alston 1989: 64-80). Further, we make God more conceivable only by moulding our idea of God more in our own image. Some degree of this is inevitable, but it is wise to minimize it if Anselm of Canterbury (§4) is right that God's greatness puts him beyond our full conceptual grasp (*Proslogion*, ch. 15). If Swinburne and Hartshorne offer more than argument by analogy, they premise that necessarily, if *x* can move *y* directly or know about *y* immediately, then *x* is embodied in *y*. This is false if telekinesis and telepathy are logically possible. For it is not plausible that while a telepath reads my thoughts or a telekinetic moves my limbs, my body houses two persons. Finally, ethical and spiritual intuitions differ greatly, and so are frail grounds for metaphysical conclusions.

Why has mainstream Western theism so wholly rejected divine embodiment? If God is the most perfect possible being, God cannot exist only as embodied in part of the universe. For if he did, a being greater than him would be possible, namely one with just his knowledge and power, but the whole universe as a body. But even (UB) renders God physically finite if (as physicists now believe) the universe is finite. If he is physically finite, God has a surpassable value and importance; were he/the universe bigger, he might well be better.

If (UB) is true, the universe is all living matter; it is one large animal. Plato (§16) was willing to say this (*Timaeus*, 30b-c), but few wish to follow him. Again, the universe includes many items whose inclusion in God seems beneath God's dignity. If the universe is God's body, flaws in the universe are flaws in God's body. If my body is flawed, *I* am flawed; we say that *I* have a bad back, not merely that my body has one. Thus flaws in the universe are flaws in God; and if there is in fact a problem of natural evil, the universe is flawed (see Evil, problem of §§1, 6). Again, if part of my body is ill, *I* am ill. But then when parts of God's body are ill, as when humans have colds, God himself is sick. Being able to be ill, however, is an imperfection.

We can damage material things. If these are parts of God's body, then we can damage God, since to damage parts of someone's body is to damage that person. We can also literally push God (or parts of God) around. Such divine vulnerability seems unbecoming. It is why the Christian doctrine of the Incarnation shocked the Greeks and provoked Chalcedonian Christology as an antidote (see Incarnation and Christology §1).

If (UB) is true, then either necessarily God exists only if embodied, or God has a body only contingently. On the first alternative, God exists contingently (Swinburne), or the universe exists necessarily (Hartshorne); both claims are highly debatable. If God exists only if embodied, the universe *is* God; it constitutes him. But if the universe is God, it would still be God if it contained one atom less. If so, it would still be God without yet another atom, and

so on, to the eventual conclusion that a universe consisting of a single atom would still be God. But a single atom is certainly destructible; hence, God is possibly destructible, and so destructible now. The universe can be caused to exist; it is quite possible that the Big Bang had a cause. So if God does not exist save as embodied in a universe, God can be caused to exist - and cannot have created the universe *ex nihilo*. Further, if we are parts of God, our freedom is a lack of divine self-control, another imperfection in God.

Finally, many scientists and philosophers think there can be other universes, not spatially or temporally connected with ours (see Cosmology §3). Suppose that there is a second universe. Then if God is our universe, he cannot have made the other. His bringing it to be, an act in our time and space, would connect that universe to ours, and so the two would not be spatiotemporally discrete after all. Nor can God have both universes as bodies. If God's thoughts in one universe are spatiotemporally connected to his thoughts in the other, then God's thoughts connect the universes, making one of what we supposed were two. But one being cannot have two spatiotemporally unconnected lifelong streams of thought. So if there can be two universes and God must be embodied, there can be a universe God did not make, and there is a possible contingent object, a second universe, that God cannot create. Further, if a universe can embody a God, then if there can be two universes, arguably there can be a second God.

The view that God can exist unembodied but is contingently embodied may escape some of the difficulties raised. But its price may be emptying (UB) of most of its content: what does (UB) mean if the objections above do not apply, and how does it differ from traditional unembodied theism?

3 Omnipresence and divine spatiality

Many rabbis called God the universe's place (*makom*). St Paul said of God 'in him we live and move and have our being' (Acts 17: 27-8). Picking up this theme, Anselm declaimed to God that 'You are not in space… but all things are in you. For you are not contained by anything but rather you contain all else' (*Proslogion*, ch. 19). For Anselm, then, God's omnipresence is his way to contain all spatial things; Anselm *may* take this containment spatially (Leftow 1989).

For the Cambridge Platonist More (§5), all substance, as such, is extended, and infinite space is in fact God's infinite extension. Bradwardine and Oresme had moved this way in the fourteenth century; Spinoza too took infinite extension to be a divine attribute (*Ethics* I, prop. 15, proof). Newton (who read More) held that God is not space, but is present everywhere, and by being everywhere makes space exist. For Newton, God, by being spatial, establishes space: space is absolute in the sense of not being reducible to *creatures'* spatial relations, but reduces to or depends on God's spatiality. For Berkeley (§§6-7), to be is to be perceived by God, and so all space is divine perceptual space, a space 'within God's mind'. Newton was not a Berkeleyan divine phenomenalist, but his claim that infinite space is God's *sensorium* also seems to make all space God's perceptual space.

For these thinkers, even if God is immaterial, he is spatially extended or space is somehow literally in God. God's omnipresence is the way God spatially includes space and creatures; it rests on God's being, or being the foundation of, space, and God is present as space is. For all save Berkeley, the whole of God is not present at any point or to any creature.

4 The omnipresence of a spaceless God

In the West, Platonism first took God to be immaterial and intrinsically spaceless (that is, able to exist even if no space exists). So Platonism first discussed a spaceless God's presence in space. Plotinus (§§3-5), whose views were most important historically, took being in to be a variety of depending on. Spatially contained objects depend on their containers. So for Plotinus, spatial containment is one kind of being in. But it is not the only kind (*Enneads* VI, 4, 2). Plotinus held that soul is not in body but body in soul, and God is not in the world, but the world in God. For God to be omnipresent, he thought, is for God to 'contain' space and the world, that is, for the whole universe to depend on God. The availability since Plotinus of non-spatial uses of 'in' and 'contain' cautions us in reading the apparently spatial language of later treatments of omnipresence.

Plotinus thought God present everywhere as a whole, because each part of space causally depends on the whole of God. He took God to be whole in the whole of space and whole in each part of space, rather than having parts occupying parts of space. Plotinus noted that even if an object controlled or conserved has parts, its conserver need not have parts, for the whole controlling power is related as a whole to each part of the controlled object, rather

than part by part. He used analogies to suggest that being whole in the whole and in each part is conceivable even apart from his causal account of being in. Light seems to be everywhere without being divided into parts; the sound of a spoken word seems to be present as a whole in an entire area and also in each part of that area, since in each part one can hear the whole sound. Plotinus also argued that an immaterial soul is present as a whole in its whole body and in each part of its body, claiming that only this can explain how the soul feels pain in all parts of the body. For Plotinus, then, to be omnipresent is to contain the universe; God's omnipresence rests on God's causal relation to the universe; and God's presence is causal, not spatial, and not by parts.

Augustine (§§7-8) brought Plotinus' views into Christian thought, taking over Plotinus' general account of omnipresence, his argument about the soul's presence in the body, and his analogies of light and sound. Again, like Plotinus, Augustine models God's presence on that of abstract entities. The whole of a universal such as blueness is present at each point in a blue surface; so, too, the whole of God is at each point of space. Making a blue area larger does not make it bluer; being bluer is a matter of intensity. So, too, God's presence varies intensively, not extensively. As wholly present in any space or thing, God need not be more present in a large area than in a small, but God is more present in a saint than in a sinner. A universal such as blueness is in space without having parts covering parts of space (the parts of a blue surface are parts of the surface but not of blueness); so, too, God. Blueness does not have as dimensions (limits of its spatial extent) the spatial dimensions of its location(s). For wherever it is located, blueness is whole (each point in a blue surface is fully blue) and yet also present as a whole outside that place (at other places, or outside space altogether); again, the same is true of God. The abstract-entity comparison suggests that an immaterial God can fill a place without being contained by it, excluding other things from it, or being intrinsically spatial or physical. Perfect-being theology finds presence as a whole everywhere a more perfect way to be present, making God more fully present at each place.

Augustine took God's creating and sustaining all things to provide a further sense (like Plotinus') in which he is present in them; Aquinas made the Aristotelian roots of this thinking plain (*Summa theologiae* Ia, 8, 1). Aristotle insists that agents move only by direct contact with what they move (*Physics* VII, 2). Aquinas (among others) reads this as implying that a 'contact of power' links any immaterial agent and its effects (*Summa theologiae* Ia, 8, 2 *ad*. 1; 52, 1). If two things touch (that is, are in contact), they are in some sense at the same place. On the doctrine of divine simplicity Aquinas (§9) and other medieval thinkers shared, God is identical to God's power (*Summa contra gentiles* II, 8). So if God's power is in some way at the place of its effects, so is God. Later medieval philosophers (such as William of Ockham §9) increasingly questioned the doctrine of contact action. If action at a distance is possible, God's acting at a place does not entail that he is in any way present there. But a more basic point is that 'contact of power' seems just a metaphor. Whether or not things can act at a distance, immaterial things in no way literally touch material things.

Aquinas inherited from Lombard's *Sentences* (I, d. 37) the formula that God is in all things by power, presence and essence. Aquinas took God's indwelling by presence to be his having full, immediate knowledge of all things, and so took God's knowledge of spatial things to provide yet another sense in which God is present to them (*Summa theologiae* Ia, 8, 3). Perhaps Aquinas' thought is that if all things are present to God's knowledge, then as 'present to' is a symmetric relation, it follows that God's knowledge is present to all things, and given divine simplicity, God is identical to God's knowledge (*Summa contra gentiles* I, 45).

For Augustine and Anselm (*Monologion*, chaps 13-14), God is omnipresent because and in the sense that he creates and rules all. For Karl Barth, God rules all because he is omnipresent: 'all divine sovereignty… is based on the fact that for God nothing exists which is… not near' (1957: 461). For Aquinas, God is omnipresent because and in the sense that he knows all things immediately. For Newton, God knows because he is present:

> The *sensorium* of animals (is) that place to which the sensitive substance is present and into which the sensible images of things are carried… that there they may be perceived by their immediate presence to that substance… there is a Being, incorporeal… intelligent, omnipresent, who in infinite space, as (if) in his *sensorium*, sees the things themselves… and comprehends them wholly by their immediate presence to himself.
> (*Optics*, query 28; appended to Leibniz and Clarke [1717] 1956)

If God's omnipresence has some truly spatial meaning, it has an independent content which lets it explain other divine attributes. If it has none, the doctrine of omnipresence reduces to a metaphor for God's omniscience and creatorhood. This reduction may not be what Scriptural authors intended. Jeremiah declaims:

‘Can anyone hide in secret places so that I cannot see him?’ declares the Lord.

‘Do I not fill heaven and earth?’ declares the Lord.

(Jeremiah 23: 24)

The suggestion seems to be that God’s knowledge rests on his omnipresence, not vice versa. Again, the religious (and even more the mystical) sense of God’s presence seems to be not just that God knows us or creates us, but that God is in some sense here with us. So something closer to literal spatial location seems needed. Spaceless-God accounts do not provide it, save by the abstract-entity analogy.

Omniscience

The concept of omniscience has received great attention in the history of Western philosophy, principally because of its connections with the Western religious tradition, which views God as perfect in all respects, including as a knower. Omniscience has often been understood as knowledge of all true propositions, and though several objections to any simple propositional account of omniscience have been offered, many philosophers continue to endorse such an analysis. Advocates of divine omniscience have discussed many problems connected with both the extent of omniscience and the relation between this property and other alleged divine attributes. Three such issues are: Can an omniscient being properly be viewed as immutable? Would an omniscient being have knowledge of the future, and is such knowledge consistent with our future actions' being genuinely free? And should omniscience be thought of as including middle knowledge? That is, would an omniscient being know (but have no control over) what other free beings would in fact freely do if placed in various different situations?

1 Omniscience and perfection

The concept of omniscience, though of considerable philosophical interest in itself, has attracted enormous attention throughout the history of philosophy primarily because of its theological connections. Most Western theists have embraced a picture of God as a being perfect in all respects, and this commitment has naturally led philosophers in this tradition to investigate the notion of noetic perfection. Such perfection is plausibly thought to entail omniscience - knowledge of everything. Hence the view that God is omniscient has been commonplace in Western monotheism.

Of course, to endorse this claim of divine omniscience is to open the door to several obvious questions. How exactly is omniscience to be understood? Of what is an omniscient being knowledgeable? And are there not reasons (related to time and human freedom) to suspect that omniscience might be a more limited perfection than one might initially have thought?

2 The analysis of omniscience

At first glance, the concept of omniscience, unlike many other divine attributes, would seem to be open to a very simple and direct analysis: a being is omniscient if and only if it knows all true propositions. Many philosophers would contend that such an analysis is indeed fully adequate. Still, questions have been raised.

Some, following Aquinas, have denied that perfect knowledge is properly thought of as propositional in structure. Our need to carve up our acquaintance with reality via discrete, complex propositions, it is argued, is a sign of our imperfection. A truly perfect knower would have no need for propositional knowledge, but instead would possess a simple and immediate intuitive awareness of reality. Many of the advocates of this position see it as flowing from the notion of divine simplicity, an attribute which has received renewed attention in recent years (see Simplicity, divine). Most philosophers, though, are reluctant to ascribe absolute simplicity to God; not coincidentally, perhaps, the view that God's knowledge is wholly non-propositional is also a minority view.

However, the analysis of omniscience offered above can also be questioned even by those who view divine knowledge as propositional. Assuming that God knows all true propositions, one might argue, his knowledge would still be imperfect if he knows *only* propositions. Three types of knowledge which supposedly go beyond the propositional are of particular interest here.

The first is *de re* knowledge, knowledge of things rather than knowledge of propositions. *De re* knowledge often appears to be present when the corresponding propositional, or *de dicto,* belief is not. For example, if JoAnn mistakenly believes that my pet iguana Willard is an alligator, then she might know *de re* of my pet iguana that he is green, even though the *de dicto* belief that my pet iguana is green is one that she rejects. Though the distinction between *de re* knowledge and propositional knowledge seems reasonable, this distinction may not require any emendation of the analysis of omniscience, since it is not clear that a being who knows all true propositions (including such truths as that Willard is an iguana) would be lacking any *de re* knowledge.

A second and similar objection to the propositional analysis of omniscience focuses on *de se* knowledge, knowledge of oneself. Such knowledge, one might contend, can be present even in the absence of the

corresponding *de dicto* knowledge. If Anastasia, hospitalized with amnesia and unaware of her name, reads an old newspaper account of her early life, she may well know *of herself* that she is in hospital, even though she does not believe that Anastasia is in hospital. Furthermore, one might question whether anyone distinct from Anastasia *could* possess the exact *de se* knowledge she has. Some defenders of the propositional analysis attempt to deal with this *de se* objection in a manner similar to the *de re* one: complete propositional knowledge, they argue, rules out any absence of knowledge which is held *de se*. Such responses call upon us to view Anastasia's *de se* knowledge as knowledge of a special type of proposition (perhaps involving her individual essence or haecceity), one which someone distinct from Anastasia could know, and one which anyone who knows all true propositions would know. Since many would question the existence of such special propositions, though, this type of response is quite controversial (for further discussion, see Wierenga 1989).

The third objection to the propositional analysis suggests that there is a distinctive qualitative dimension to certain kinds of knowledge which is ignored by that analysis. For example, even the most exhaustive propositional knowledge about chocolate leaves out a crucial element in a complete knowledge of chocolate - namely, knowing what chocolate tastes like. A being who knew all true propositions about chocolate, but who lacked actual acquaintance with its taste, could not be said to have perfect knowledge. Various responses to this objection are available. Some defenders of the propositional analysis flatly deny that experience of the sort suggested is required for one's knowledge of chocolate to be complete; others agree that we would expect a perfect being to possess such qualitative awareness, but deny that it should be thought of as knowledge in anything more than an analogical sense.

Though the three objections discussed here pose significant problems for the propositional analysis, problems sufficient to have led some philosophers to complicate or abandon it, none is clearly decisive, and many advocates of the propositional view remain. Whatever one's verdict on this matter, though, one who embraces the belief that God is omniscient faces many difficult questions concerning both the scope of omniscience and the compatibility of divine omniscience with other attributes commonly ascribed to God.

One such question is how a God who has perfect knowledge of our ever-changing world could himself be utterly immutable. Since immutability itself is often viewed as a perfection, and since it seems to be entailed by two other attributes (simplicity and eternity) frequently deemed essential to a perfect being, many theists are strongly inclined to view God as unchanging (see Immutability). Yet complete knowledge seems to require change on the part of the knower whenever there is change on the part of that which is known. In the face of this objection, some theists have abandoned the view that God is utterly immutable; they suggest that so long as God is stable in his powers, constant in his providential care for his creatures, resolute in his intentions, and so on, we need not be concerned by trivial changes in his noetic activity. Other theists have denied that the argument forces us to jettison immutability. For example, advocates of divine eternity have maintained that God's eternal perspective would allow him (in a sense) simultaneously to view events that are not simultaneous from our perspective; hence, his knowledge of all such events need imply no change in him (see Eternity). Though fraught with the potential for (and, as critics see it, the actuality of) paradox, this view has been developed with ingenuity by several writers (see especially Stump and Kretzmann 1981).

In addition to the question concerning immutability, two other significant issues connected with omniscience have received much critical attention. First, does an omniscient being know what we *will* freely do in the future circumstances which will in fact obtain? Second, does an omniscient being know what we *would* freely do were other circumstances to obtain?

3 Omniscience, foreknowledge and freedom

If God is all-knowing, it seems reasonable to assume that he knows not only what did happen and what is happening, but also what will happen. But how could comprehensive divine foreknowledge be compatible with the contingency of what is foreknown? In particular, how could our actions be free, be such that we could have done otherwise, if an infallible God knew in advance what we would do? This question has vexed some of the greatest minds in Western history, from the Greek tragedians (especially Sophocles) to such Christian luminaries as Augustine (§§6, 10), Aquinas and Jonathan Edwards (§2); in contemporary philosophy of religion, it remains perhaps the most-discussed problem connected with the attribute of omniscience.

Though the problem has been explicated in many different ways, perhaps its strongest form can be presented as follows. Suppose God knows that I will perform a certain action tomorrow - for example:

(1) God knows that I will go horseback riding tomorrow.

Clearly, this cannot be knowledge that God has recently acquired; if his omniscience is (so to speak) a stable feature, it must be knowledge he has always possessed. So:

(2) God knew last year that I will go riding tomorrow.

But (2) tells us about what was true in the past, and we generally think that what happened in the past is necessary - not, perhaps, logically necessary, but necessary in the sense of being fixed, settled and beyond anyone’s control. In this sense of necessity (which is variously called temporal necessity, accidental necessity and necessity *per accidens*), it follows from (2) that:

(3) It is necessary that God knew that I will go riding tomorrow.

Of course, no one can know something which is false. Indeed, in the case of God, traditional theists insist that God cannot so much as believe something which is false. So from (3) it follows that:

(4) If God knew that I will go riding tomorrow, then I will go riding tomorrow.

Now, (3) tells us that a certain truth is beyond anyone’s control, while (4) spells out a logical consequence of that truth. But surely what follows logically from something which is necessary must itself be necessary in that same sense. If (3) and (4) are beyond dispute, then, it follows that we are also saddled with:

(5) It is necessary that I will go riding tomorrow.

And since what I do by necessity is not something over which I hold the reins of power, it follows that my act of riding tomorrow is beyond my control, and hence will not be a free action. As this argument form could evidently be unharnessed from our equine example, the conclusion to which we are led is that no action can be free if God possesses foreknowledge.

Responses to this argument are many and varied; virtually no step is beyond dispute. Some have reacted by accepting the conclusion that foreknowledge rules out freedom and consequently rejecting the claim that our actions are free. Others who embrace the incompatibilist conclusion (the thesis that foreknowledge and freedom are incompatible) react in the opposite way: instead of denying freedom, they deny foreknowledge, and so deny that a premise such as (1) is ever true of a free action. Rather than denying that God is omniscient, many such incompatibilists suggest that omniscience does not require foreknowledge. Just as omnipotence does not entail the power to do what cannot be done (see Omnipotence §§1-3), so, they argue, omniscience does not include the power to know what cannot be known; since foreknowledge of free actions has been shown by this argument to be impossible, we ought not expect an omniscient being to have such foreknowledge (see Hasker 1989). Other incompatibilists, especially those favourably disposed towards the notion of divine eternity, criticize the argument’s blatantly putting God in the temporal realm. No divine cognitive activity, they insist, takes place in time, and hence the use of ordinary tensed propositions to refer to such activity is out of place. For such incompatibilists, (1) and especially (2) ought to be rejected.

Compatibilist rejoinders (that is, responses by those who see foreknowledge and freedom as compatible) come in two basic forms. The first of these is to deny that (3) follows from (2). Many facts about the past - those commonly called hard facts about the past - are exclusively about the past, and these do have the kind of necessity at issue in this discussion. But (2) is not exclusively about the past; it is about the future as much as it is about the past, and hence qualifies as only a soft fact about the past. Unlike hard facts about the past, soft facts need not be seen as necessary; hence, (3) does not follow from (2), and the argument dissolves.

This type of response, which draws its inspiration from William of Ockham, is often referred to as the Ockhamist response. An amazing amount of literature on this position has been generated and a large number of variations on it proposed. Various ways of understanding the notion of temporal or accidental necessity have been offered, and numerous means (often of great technical complexity) of distinguishing hard from soft facts have been formulated

(see Plantinga 1986). Some commentators have even suggested that the hard/soft distinction may be too coarse for the problem at hand: even if (2) turned out to be a soft fact about the past, it might well have a hard 'core' - such as the fact that God *believed* last year that I will ride tomorrow - which is sufficient for an analogue of the incompatibilist argument to succeed.

The second basic form of compatibilist response is to deny that (5) follows from (3) and (4). More generally, such a response denies that accidental necessity is closed under entailment or logical implication; that is, it suggests that an accidentally necessary proposition can entail a proposition that is not accidentally necessary. Such a response, which was suggested by the sixteenth-century Spanish theologian Luis de Molina (§§1-3) and has come to be known as the Molinist response, seems most plausible when accidental necessity is understood as applying to those truths which are beyond our ability to cause to be false (see Molinism). So understood, (3) seems clearly true (at least as long as we grant that we lack causal power over the past), as does (4), but (5) does not clearly follow. If we already knew that I had no power to cause my *not* riding tomorrow, the inference might be uncontroversial; but, of course, my causal impotence with regard to the future is what the argument is trying to prove and hence can hardly be assumed in this context.

It has been suggested that whether an Ockhamist or a Molinist response to the argument is more appropriate depends upon how accidental necessity is analysed. Under some interpretations of necessity (ones which equate the accidentally necessary with that which I cannot cause to be false), (3) will follow from (2), but (5) will not follow from (3) and (4). Under other interpretations (ones which equate the accidentally necessary with that which would be true no matter what I might do), (5) will be derivable from (3) and (4), but (3) will not follow from (2). On this view, the incompatibilist argument derives whatever plausibility it has from equivocation.

4 Omniscience and middle knowledge

Closely related to the issues discussed in the preceding section is the question of middle knowledge. Molinists have claimed that between God's natural knowledge (of necessary truths not under his control) and his free knowledge (of contingent truths under his control) is a third category of divine knowledge called middle knowledge - knowledge of contingent truths not under God's control. The most significant components of middle knowledge, according to Molinists, are the counterfactuals of creaturely freedom. These are conditional statements specifying, for any creature God might create and any situation in which that creature might be placed and left free, what it would freely do if placed in that situation. Molinists insist that, while there are truths of this sort, God would have no control over them because such control would conflict with creatures' being free in the full-fledged libertarian sense.

As Molinists see it, counterfactuals of creaturely freedom help us to understand how it is that God knows the future. Prior to any creative decision on his part, God knows via middle knowledge how any set of creatures he might create would freely respond to any creative action he might perform. Using this knowledge, God can decide which beings he will create in which situations. Given this decision, he can know immediately what free actions will in fact be performed. Assuming that all other facts about the future result either from necessary truths or from other divine decisions (for example, regarding which causal laws to establish and when, if ever, to intervene in their normal operations), it follows that God's foreknowledge would be not only complete, but also in no sense dependent upon his observing or being affected by that which he foreknew.

If God possesses middle knowledge, though, its value to him far exceeds its ability to produce foreknowledge. For central to the tradition is the claim that God not only knows what will happen, but directs the course of events; he is a sovereign, provident deity, not an all-knowing but passive witness to earthly occurrences. Middle knowledge gives God the means to exercise such providence in a very strong sense, for it allows him a clear way to incorporate even the free actions of his creatures in a complete and specific providential plan.

The advantages middle knowledge would offer in constructing a coherent picture of an omniscient God are widely, though not universally, acknowledged. Also recognized is the fact that there is a strong *prima facie* case for thinking that an omniscient being would know the sort of truths which compose middle knowledge. On the surface, it surely looks as though counterfactuals of the sort at issue - such as 'If I were to go to the doctor tomorrow, the nurse would take my blood pressure' - have a truth value, one which we often know and upon which we base our actions. Even when we do not know whether such a conditional is true or false, our natural assumption is that there

is a fact of the matter here, a fact which we would like to know and which any omniscient being would have to know.

Despite its theoretical fecundity and initial plausibility, middle knowledge has been the subject of enormous controversy, and several powerful arguments have been marshalled against it. Some critics, following the Thomistic attack initiated by Molina's contemporary Báñez, have charged that the Molinist position is founded on a view of freedom which is metaphysically and theologically misguided. God's sovereignty, they have contended, would be compromised were he powerless in the face of contingent truths about his creatures. A careful analysis of the notion of freedom, they suggest, allows us to see the counterfactuals in question as subject to divine control.

A more common line of attack among contemporary philosophers of religion grants Molinism its libertarian picture of freedom, but insists that this picture requires us to deny the possibility of true counterfactuals of creaturely freedom. For what, it is asked, could ground such a truth? If the action in question is truly free, no element of the situation could necessitate its performance; nor, in many cases, will there be any activity in the past, present or future of the actual world which can be seen as grounding the counterfactual, for most such conditionals will refer to creatures and/or situations which are never actual. There are truths, such critics grant, about what creatures *might* do if placed in certain circumstances, and perhaps even truths about what they *probably* would do, but truths of this sort fall far short of providing God with the kind of foreknowledge and providential control championed by the Molinist. While some critics view the apparent failure of Molinism with regret, others see it as a cause for celebration; a God who needs and is willing to take risks in interacting with his creatures is actually preferable, they suggest, to the all-controlling, manipulative God of the Molinists.

Molinists have offered thoughtful responses to such critics. Abandoning the libertarian picture of freedom, they have argued, is philosophically indefensible and theologically dangerous, in so far as it would render God ultimately responsible for evil. Some Molinists have responded to the grounding objection by questioning either the meaning or the truth of the claim that all propositions need grounds; others have suggested that counterfactuals of creaturely freedom do indeed have grounds, though (as with propositions about the past or the future, or about what is metaphysically possible) we might not find such grounds at the present time or in the actual world. Finally, Molinists have charged that the risk-taking, playing-the-odds picture embraced by some of their critics gives us a God who is little more than 'the bookie than which none greater can be conceived', a deity far inferior to that required by the Western religious tradition.

Ontological commitment

A person may believe in the existence of God, or numbers or ghosts. Such beliefs may be asserted, perhaps in a theory. Assertions of the existence of specific entities or kinds of entities are the intuitive source of the notion of ontological commitment, for it is natural to think of a person who makes such an assertion as being 'committed' to an 'ontology' that includes such entities. So ontological commitment appears to be a relation *that holds between persons or existence assertions (including theories), on the one hand, and specific entities or kinds of entities (or ontologies), on the other.*

Ontological commitment is thus a very rich notion - one in which logical, metaphysical, linguistic and epistemic elements are intermingled. The main philosophical problem concerning commitment is whether there is a precise criterion *for detecting commitments in accordance with intuition. It once seemed extremely important to find a criterion, for it promised to serve as a vital tool in the comparative assessment of theories. Many different criteria have been proposed and a variety of problems have beset these efforts. W.V. Quine has been the central figure in the discussion and we will consider two of his formulations below.*

Many important philosophical topics are closely connected with ontological commitment. These include: the nature of theories and their interpretation; interpretations of quantification; the nature of kinds; the question of the existence of merely possible entities; extensionality and intensionality; the general question of the nature of modality; and the significance of Occam's razor.

1 Fundamental problems

The intuitive source of the notion of ontological commitment is people asserting things to exist. It may thus be thought of as a *binary relation* between persons or assertions of existence and the entities or kinds of entities they assert to exist. The main philosophical problem concerning commitment is whether there is a precise criterion for detecting commitments in accordance with intuition. Anyone who seeks a criterion of commitment must first decide what sorts of entities may properly stand in the positions of the relation. Unfortunately there are at least *five* significant candidates for occupying its first position: persons; acts of uttering (or inscribing); utterances (or inscriptions), that is, the actual 'tokens' produced; sentences uttered (or inscribed), that is, the 'types' of which tokens are produced; and propositions (which on some accounts are often expressed on occasions of utterance or inscription). And there is a similarly diverse range of candidates for the second relatum. So there is a daunting array of seemingly different ways to see commitment as a binary relation.

An encouraging thought about this proliferation is that it may not ultimately matter which approach one takes because, given any plausible choice, the relation may be thought of as holding *derivatively* between pairs of the unchosen sorts in a more or less natural way. It may also be that moving to a ternary (and so on) treatment would help absorb some of the complexity, but commitment is typically viewed as a binary relation, and we will follow that precedent here.

Another difficulty is that our intuitive talk of commitment is crucially ambiguous. Sometimes we speak as if a person who says there are whales is (thereby) committed to the existence of mammals, sometimes not. So, there is a sense of commitment that 'tracks entailments' and one that does not. Both senses are surely legitimate, but we should decide which we are discussing at the outset. If we distinguish thus between '*prima facie*' and 'all-in' commitment, then it is fair to say that the discussion provoked by W.V. Quine mainly concerns the former. This is not surprising given his famous antipathy to essential properties and analytic truth, as well as his explicit claims that the notion of commitment belongs to the 'theory of reference' (and not to the 'theory of meaning'). But we will see that some of Quine's formulations can seem more suitable for assessing all-in commitment than *prima facie*.

Quine's stated criteria are sometimes meant to reveal commitment to *specific* entities, sometimes to *kinds* of entities. We will focus on the latter. Here are two representative examples:

> (1) to say that a given existential quantification presupposes objects of a given kind is to say simply that the open sentence which follows the quantifier is true of some objects of that kind and none not of that kind.

(Quine 1953a: 131)

> (2) entities of a given sort are assumed by a theory if and only if some of them must be counted among the values of the variables in order that the statements affirmed in the theory be true.

(Quine 1953b: 103)

There is a serious problem of interpretation for any criterion intended to apply to theories. (This includes (1), for Quine's mention of open sentences following quantifiers reveals that he is thinking of certain sorts of formal theory.) The problem is that we use 'theory' in at least three different ways. First, we attribute 'informal theories' to people on the basis of their natural-language claims. Then we 'represent' these informal theories formally. Here the canonical notion is that of an (axiomatic) first-order theory along with an 'interpretation', which consists of a non-empty domain (the 'range' of quantifiable variables) plus an assignment of 'extensions' based on that domain to the nonlogical symbols of the theory. Note that we have already spoken of the purely syntactic component as a 'theory', but we also regard the syntax plus the extensional semantics as an 'interpreted theory'. So an unqualified use of 'theory' could mean any of three different things.

Now it seems almost nonsensical to think of a purely syntactic object (such as an uninterpreted sentence or theory) as ontologically committed to anything (except perhaps the syntactic elements that comprise it). Unfortunately this is the most literal construal of (1). Another construal makes the interpreted theory (or sentence, and so on) bear the commitment. This makes much better sense, but it may not make for a much better criterion. What (1) does under this understanding is, in effect, to define a certain metalinguistic relation term, 'presupposes' (see Presupposition). The relation this term expresses is evidently ternary - it relates interpreted closed sentences, objects (from the domain) and (somehow) *kinds*. The definition utilizes the notions of a formula with one free variable, the satisfaction relation (understood as relating objects and formulas - Quine's 'true of'), objects and (somehow) kinds. So (1) offers a new piece of terminology in the metatheory of interpreted first-order theories, enhanced by whatever is needed to talk about kinds in whatever way is intended. To this extent it is harmless enough, but it is not clear what it has to do with intuitive commitment. Notice that on its basis we may distinguish two sorts of objects in the domain of a theory: those that are of kinds 'presupposed' by at least one existential sentence; and, as may occur, those that are not. But any theory with both sorts of entities is already committed to all of them in a far more basic way since they are all essential components of that theory. No theory without them is the same theory.

It may therefore seem best to view (1) as directed to the case of informal theories, and the same may be said of (2). The intuitive idea is perhaps that the 'ontology' of an interpreted formal theory is 'transparent': It simply consists of the members of its domain of interpretation (or a readily distinguishable subset of them). So one might hope to reduce the hazy question of the commitments of informal theories to the transparent case of their formal representatives. But if the commitments of a given informal theory are unclear, then it would seem that the choice of its formal representative must also be unclear. So it appears that any criterion conceived in this way cannot work: to apply it we must first find a representing theory, but we cannot do this unless we already know the informal commitments.

The search for a criterion to apply to *theories* may thus seem fated to produce either near nonsense, triviality or practical futility, depending on what is meant by 'theory'. This would not be welcomed by Quine, especially since the original idea was to find a neutral means for assessing something not always clearly in view. It was to help us compare theories, sometimes with something like Occam's razor in mind. (Of course there may be a criterion for informal theories that makes no similar appeal to formal representatives.)

2 Problems of detail

We now consider some problems that arise from the details of (1) and (2). A serious defect of (1) is that it offers no means of assessing informal theories that make false existence claims. Since there are no unicorns, there is no interpreted theory the domain of which contains unicorns, and so there is none with unicorns available to satisfy relevant open sentences.

(2) offers an improvement over (1) in just this respect. For it may be seen as ruling that there *must* be some unicorns in the domain of *any* interpreted theory that would be a suitable representative of the informal theory, and

there may be a way of understanding this that makes no intuitive commitment to unicorns.

Now let us return to the matter of whales and mammals. It is clear that if the informal claim that there are whales receives a suitable (interpreted) first-order formulation, then a relevant open sentence will be true of some mammals and not true of any non-mammals. So (1) finds the informal theory committed to mammals as well as to whales. Whether (2) has the same consequence evidently depends on whether whales *must* be mammals, not (as in (1)) on whether they actually are mammals. So a philosopher who accepts (2) and, like Quine, denies that any entities have any non-trivial essential (or necessary) properties may claim that the distinction between *prima facie* and all-in commitment is a distinction without a difference (see Essentialism).

But this means there is a further difficulty in trying to evaluate Quine's formulations in the style of (2): they yield different results depending on the background philosophical views of the person applying them. When Quine applies (2) to an informal theory of whales, he concludes that it is not committed to mammals. But when an essentialist applies it, the conclusion is the opposite.

Formulations such as (1) and (2) reveal the influence (and importance) of a period that featured intense work in the areas of extensional formal semantics and the axiomatization of both scientific and philosophical theories. Such criteria are fairly characterized as seeing existential quantification as the source (and signal) of ontological commitment. They may be seen as differing elaborations of the theme expressed in Quine's famous slogan, 'To *be* is to be a value of a variable' (1939). Quine would later adopt a somewhat different perspective on the matter, the perspective of 'ontological relativity', which we will mention below. But there remain two very general criticisms of efforts in the quantificational spirit that merit separate discussion.

3 Two further problems

For a time the influence of Tarskian formal semantics was so great that it must have been difficult to imagine that any essentially different treatment of quantification could be defensible. But there is a coherent alternative called the substitutional interpretation. On this interpretation the semantics of a first-order language includes a non-empty set of terms of that language called the 'substitution class'. An existential quantification is counted true if and only if there is a member of the substitution class such that the result of removing the quantifier and replacing all resulting free occurrences of its variable by that member is true. So the truth-conditions for the quantifiers make no appeal to a domain of (potentially) extra-linguistic entities. Depending on how truth-values are assigned to atomic sentences - and one possibility is by sheer stipulation - a given substitutionally interpreted theory may have no intuitive ontological commitment beyond the constituents of the language itself, the truth-values, and perhaps some simple sets (including functions) of these entities.

The usefulness of substitutional quantification for representing informal theories may be debated (see Quantifiers, substitutional and objectual). One may ask whether the concept of truth embodied in a given substitutional theory appropriately matches the one implicit in a given informal theory. If the intuitive verdict is that the informal theory has non-trivial extra-linguistic commitment, then a substitutional theory lacking such commitment will be metaphysically inadequate (though it might get the truth-values right). But there remains the simple fact that the substitutional interpretation is perfectly coherent. From this it appears to follow that the mere assertion of an existential sentence does not provide a sufficient condition for non-trivial ontological commitment. So an adequate criterion of commitment should not presuppose that it does. The very existence and coherence of the substitutional interpretation thus creates a real difficulty for 'quantificational' criteria in the spirit of (1) or (2).

It has often been claimed, for one reason or another, that commitment is an 'intensional' notion (see Intensional entities §1). The main reason why (2) improves upon (1) is that it contains the word 'must'. But this suggests that the improvement is gained only at what Quine must see as great cost, namely, by exploiting the notion of *necessity*, which belongs to the theory of meaning. For it is natural to interpret the condition stated in (2) as meaning that it is necessary that if the statements affirmed in the theory are true, then objects of the required sort are values of its variables.

Others have found intensionality not in an appeal to necessity but in the (claimed) 'referential opacity' of the commitment relation itself, that is, in the resistance of its second position both to the substitution of coreferential expressions and to existential generalization. Commitment to Twain does not entail commitment to Clemens; nor does commitment to unicorns (*or* horses) entail there being entities to which one is committed. (Note that a

plausible claim of opacity can only be made concerning *prima facie* commitment.)

Here is a further (but related) reason to suspect intensionality. Suppose we try to state a criterion in which the condition expresses a binary relation between persons or theories (and so on) and something else. What are the plausible candidates for the second relatum? Consider first the theory that simply says there are horses. Well, there *are* horses, but the theory is not committed to any of them (either individually or collectively). One natural thought is that the second relatum is the property (or kind), being a horse. Accordingly, to say that the theory is committed to horses would mean that it cannot be true unless the property is instantiated. But properties are intensional entities. (In the case of commitment to specific entities, 'possible objects', including *merely* possible objects, are natural candidates analogous to properties.) There are other possibilities, but it has been argued that any adequate relational treatment must be intensional.

Yet another approach sees theories not as linguistic or quasi-linguistic entities, whether formal or informal, but rather as propositions (or sets of propositions). Then a theory is committed to, say, unicorns if it entails the proposition that unicorns exist. This approach is intensional because propositions are intensional entities. (It also appeals to entailment, which is usually (though not universally) thought to rest on necessity.)

So the suspicion of intensionality may arise for a number of reasons. But the intensionality always seems to flow from one of two somewhat related sources. The first is the classical problem of explaining how we can either assert or deny the existence of things that in fact do not exist. The other is that we are treating *prima facie* rather than all-in commitment. The (claimed) intensionality of commitment is not in itself disturbing, but it was vexing for Quine because of his general aversion to the intensional.

4 Translation and triviality

The possibility that an adequate criterion of commitment would somehow be 'trivial' arose in §1. Remarkably enough, it also surfaced in Quine in the wake of his important doctrines of 'ontological relativity' and the 'inscrutability of reference'. Details of these positions cannot be discussed here, but their effect on the matter of a criterion should be mentioned.

The key effect is to cast the question of a criterion as one concerning *translation*. Theories are stated in languages. An ontological criterion must also be stated in a language. For our purposes, the language of a criterion may be viewed as a technically enhanced version of an appropriate fragment of English. Call such a language E^*. Now it seems clear that if the question whether a theory T is committed to entities of kind K can be settled at all, then it can be settled as follows: simply translate the assertions (or theorems) of T into E^* and see whether the results include 'There exist objects of kind K' (where 'There exist' is understood referentially).

For reasons flowing from the aforementioned doctrines, there is a sense in which Quine does not regard this as 'settling' the question of T's ontology, because he thinks 'There exist objects of kind K', in E^*, is itself ontologically indeterminate. But he also thinks that this is an indeterminacy that cannot be removed and should not be lamented.

Any such 'translational' criterion can easily seem trivial. For either we already know the commitments of T, and so have no need for it, or else we do not, and so cannot apply it. Yet it seems perfectly natural and correct independently of the Quinean doctrines and, in particular, independently of their implication that it does not settle the question of a theory's commitment.

Ontology

The word 'ontology' is used to refer to philosophical investigation of existence, or being. Such investigation may be directed towards the concept of being, asking what 'being' means, or what it is for something to exist; it may also (or instead) be concerned with the question 'what exists?', or 'what general sorts of thing are there?' It is common to speak of a philosopher's ontology, meaning the kinds of thing they take to exist, or the ontology of a theory, meaning the things that would have to exist for that theory to be true.

1 Existence and being

Since so many central debates of philosophy concern what types of things exist, scrutiny of the arguments used in them was bound to lead to investigation of the concept of existence and its logic. The most famous case of this kind is the Ontological Argument for the existence of God , and one of the most famous moves in the ensuing debate is Kant's claim that existence is not a property or predicate of existing things: 'cats exist' clearly tells us something, but it does not tell us of things which, in addition to being furry, feline and fleet of foot, have the further property of existence (see God, arguments for the existence of §§2-3; Existence).

This point, with which modern logic agrees, may teach us to formulate 'cats exist' as 'there are things which are cats' - in which it doesn't even look as if existence is functioning as a predicate. But many will think that this does not take us very far. It does not tell us how to describe the difference between a world in which cats exist and one in which they do not - other than by repeating the formula 'there are cats'; it will not advance our understanding of what it is for something to exist. Nor will it touch the somewhat dizzying question 'why does anything exist, rather than nothing?'.

Some philosophers, however, have taken an interest in existence or 'being' (as it tends to appear in their works or in the English translations), not because it appears as part of so many philosophical claims but because they take it for the central concept of philosophy. The most prominent examples are, in antiquity, Parmenides, and in the twentieth century Martin Heidegger.

2 What is there?

In its characteristically philosophical form, this is not a question of detail (for example, are there mammoths?) but about the most general *kinds* of thing: are there universals, or only particulars? - is there mind or spirit, or is there only matter? - is there anything that exists without being in space and time? Thus the debate on the first of these questions between Platonists and nominalists, or on the second between idealists and materialists, might in each case be described as a difference of opinion about the correct ontology. So might the conflict over whether values are objective aspects of reality, or rather 'in the eye of the beholder', a matter of how we react to things rather than the things themselves (see Emotivism; Projectivism).

The questions 'What kinds of thing *ultimately* exist?' or '… *really* exist?' or '… exist *in themselves*?' are even more characteristically philosophical forms of the general ontological question. To understand what usually lies behind these additional terms one needs a grasp of (1) the concept of a *reduction* and (2) the distinction between appearances and things-in-themselves.

Reduction. Berkeley famously claimed that material objects were just collections of 'ideas' (see Berkeley, G. §3). He did not mean that there were no chairs or tables, but that such things did not have a material, non-mental component; what really existed was all mental. There are spirits and their ideas, and we speak of chairs and so on when the latter occur in familiar, stable groupings. In modern terminology, he was claiming that material objects can be *reduced to* ideas. There are other common examples. In political discourse we often speak of what a particular state has done - but without having to suppose that there are such things as states distinct from the individual people who compose them. A once-popular thesis about the nature of mind was that there is nothing but bodies and their behaviour, and that words apparently naming mental states and happenings are just convenient ways of indicating types of behaviour (see Behaviourism, analytic; Reductionism in the philosophy of mind).

Things-in-themselves. We may distinguish between the way a thing appears, which will depend partly on the faculties and situation of whoever is perceiving it, and the way it is, independently of how anyone perceives it. The

latter is the thing-in-itself. The terminology was made instantly famous by Kant, arguing that space and time (and therefore everything in space or time) were merely the way in which a non-spatiotemporal reality, things-in-themselves, appeared to humans (see Kant §5).

3 Ontological commitment

The notion of ontological commitment has come to prominence in the second half of the twentieth century, mainly through the work of Quine (see Quine, W.V. §5). On Quine's view the right guide to what exists is science, so that our best guide to what exists is our best current scientific theory: what exists is what acceptance of that theory commits us to.

But what is that? How do we determine what existents the acceptance of a given theory commits us to? Quine proposes a criterion, often summarized in the famous slogan 'to be is to be the value of a variable'. We are to see what types of thing are quantified over when the theory is stated in canonical form with predicate calculus as the underlying logic; the theory's ontological commitment is precisely to things of those types. This line of thought has given rise to much discussion (see Ontological commitment).

Ontology in Indian philosophy

All Indian philosophical traditions are deeply engaged with ontology, the study of being, since clarity about the nature of reality is at the heart of three intimately connected goals: knowledge, proper conduct and liberation from the continued suffering that is part of all human existence. The formulation of a list of ontological categories, a classification of reality by division into several fundamental objective kinds, however, is less widespread. There is little room for a doctrine of distinct, if related, ontological categories in a philosophical school that takes reality as one, even less if that one lies beyond description. If the phenomenal world is but illusory appearance, as, for example, in the Vedānta of Śaōkara, then a determination of kinds of entities does not recommend itself as a means to adequate analysis of the world. Even the Sāōkhya tradition's realism reduces the world to an evolution from two fundamental entities, spirit and matter. Categories make sense within the context of a pluralistic realism, an analysis of the world that finds it to be composed of a multiplicity of real entities. Such a view is found to some extent in Jaina philosophy, but is primarily defended and developed in the Nyāya-Vaiśeṣika school.

The Nyāya-Vaiśeṣika categories are seven: substance, quality, motion, universal, particular, inherence and not-being. While all are understood as real entities and objects of knowledge, substance is most fundamental as each of the others in some way depends on substance. Substances are nine: earth, water, fire, air, ether, time, space, self and mind. The first four are atomic: they may combine to form macroscopic substance, such as a clay pot, but in incomposite form they are indestructible atoms, as are the last two. Ether, time and space, likewise indestructible, are unitary and pervade all. In its irreducible parts, all substance is eternal; every composite whole is a destructible substance.

A relation of containment, called inherence, structures the categories. The qualities, actions and universals by which we might characterize a pot inhere in it. They are distinct entities from the pot, yet cannot exist apart from their underlying substrate. Composite substances like a pot are also contained in their parts by inherence, but the smallest parts, eternal substances, exist independently as receptacles that contain nothing. A whole, greater than the sum of its parts, is said to inhere in the parts while the parts are the inherence cause of the whole.

Eternal substance, the ultimate substrate of all, is a bare particular. An entity that is nothing but a receptacle for other entities, it furnishes criteria for separability and individuality, but cannot be defined in itself apart from others. This aspect of the concept of substance leads later Nyāya-Vaiśeṣika into extensive analysis of relations and negation.

1 Categories

While ontological speculation lies at the heart of all schools of classical Indian thought, a great portion of the tradition is not conducive to a doctrine of ontological categories. Categories provide a means to analyse the world according to the distinct kinds of entities that are the ingredients of all reality. The tradition growing out of the philosophical treatment of the Vedas in the Upaniṣads, in which all questions of ontology press towards the transcendent and the being of the phenomenal world is doubted and rejected as an illusion, ought to have limited use for such a tool. The arguments of Buddhist thinkers taking all phenomena as the only existence, a flux with no underlying reality, also leave no place for a classification of discrete kinds of realities. A theory of categories develops not in an idealism or nominalism, but presupposes some kind of pluralistic realism.

The most extensive system of ontological categories in classical Indian thought was worked out over the course of several hundred years by the Nyāya-Vaiśeṣika school. Traditionally this begins with the *Vaiśeṣikasūtra* of the legendary Kāṇāda, followed by the commentary of Vātsyāyana (fifth century AD) and the work of Praśastapāda (sixth century). The resulting most widely accepted list contains seven categories, the first three of which each comprise a standard list of members, as follows: (1) substance, which includes earth, water, fire, air, ether, time, space, mind and self; (2) quality, which includes colour, taste, smell, touch, number, measure, separateness, conjunction, disjunction, priority, posteriority, cognitions, pleasure, pain, desire, aversion, volition, gravity, liquidity, viscidity, disposition, merit, demerit and sound; (3) action, which includes throwing upwards, throwing downwards, contraction, expansion and going; (4) universal; (5) particularity; (6) inherence; (7) absence or nonexistence.

This list was appropriated in part by other schools, notably Jaina thinkers, who took substance as an all-inclusive category that is further subdivided and concurred to an extent with Vaiśeṣika in positing real, individual souls. The Jaina tradition could be viewed as an expansion of Sāōkhya dualism: in addition to conscious but formless reality and nonconscious material reality, it recognizes a nonconscious but formless reality (see Jaina philosophy §1; Sāōkhya §2). This is a doctrine of substance, classifying three kinds of permanent realities, and not a doctrine classifying appearances that are nothing in themselves, but are derivative manifestations of a transcendent reality. In addition to conscious reality, souls, and nonconscious matter, atoms and their aggregations, there are four kinds of nonconscious yet immaterial substance, each a medium for change. These are the media of motion, rest, space and time. All reality is identified with substance, which is seen as unifying permanence and impermanence. This all-inclusive category of substance is designed to explain how an entity can remain a real, self-same individual throughout change. Mīmāṃsāalso makes use of the notion of substance. In general, however, where categories appear in Indian thought outside the Nyāya-Vaiśeṣika tradition, they are ancillary tools, not the root of ontology. Such is the view of Vedāntin compendia of philosophy - short works that classify and summarize other schools - in considering Nyāya-Vaiśeṣika early and primitive, containing useful instruments for analysis but no insight into truth.

In the philosophical vocabulary of European languages, ‘category’ is a derivative of the Greek word first appropriated for philosophical jargon by Aristotle (§7). *Kategoria*, from the verb *kategorein*, literally ‘to speak in the marketplace’, entered the language of jurisprudence meaning ‘to accuse’, that is, to say something about someone. Aristotle adopted it for a classification of the different ways to say things about other things, a classification of kinds of predicates. A philosophical claim lies behind Aristotle’s method. If language is thought reflecting what there is, then the structure of language is the key to the structure of reality. The Indian term for ‘category’, *padārtha*, the object or meaning (*artha*) of a word (*pada*), suggests a related notion. Though it is not in the Vaiśeṣika texts, some Indian grammarians drew a connection between the first three categories, substance, quality and action, and the distinction between noun, adjective and verb. Certain Vaiśeṣika arguments do rely explicitly on word meaning, claiming that words could have no meaning if universals were not real entities.

All seven categories are all mentioned in the *Vaiśeṣikasūtra*, although the word we translate as ‘category’, *padārtha*, occurs only once, in a disputed verse where it designates the first six. The term does not become clearly established until Praśastapāda’s commentary on the *Vaiśeṣikasūtra*, the *Padārthadharmasaōgraha (Compendium of Properties of the Categories)*. The categories are not only the meaning or object of words; they represent a classification of all being, a definitive listing of the various kinds of things that exist. Each category represents a distinct kind of entity.

The reality of each category rests on three aspects: individual unity, causality and independence. (1) Whatever is a real entity is a separate individual, knowable as such, even if it cannot exist apart from something else. (2) Each category of thing is known as a cause: substance causes substance, quality quality, action action, universal and particularity cause cognition, particularity in an ultimate sense causes the individuality of eternal substances, and inherence causes subsistence in. (3) Most individual realities are dependent on or contained in something else, with the chain of dependence going back to independent eternal substances.

This does not yet give much clue as to what each category is. That task requires patience, since each category, while separate, is largely defined through relations to other categories.

2 Relations

Despite the emphasis on the particularity (*viśeṣa*) of the individual, the source of the name Vaiśeṣika, none of the categories can be adequately grasped without reference to others. Śrīdhara (tenth century) writes that the categories ‘become objects and properties with reference to one another’ (*Nyāyakandalī,* comment to III.1). In Vaiśeṣika all relations obtain between two entities. Most significant to understanding the structure of the categories is the relation called inherence. Itself a category, inherence informs the nature of all categories. There are two central aspects to its definition. It is a permanent relation, in contrast to the relations of conjunction and disjunction. The conjunction of two objects - two pebbles in contact, say - can soon be dissolved. Inherence, on the other hand, is a relation that persists until one or both of the relata are destroyed. Furthermore, inherence is explained by the metaphor of containment. In an inherence relation, one of the individuals is always contained by the other, which is its container. The contained is said to inhere in the container.

The relation of contained to container is the primary example of a relation of superstratum to substrate. (It is not, however, the only one. Other relations, including conjunction when one object is on top of another, are also of this general sort; see §9.) Common synonyms for the term ‘substrate’ (*ādhāra*) include ‘locus’ (*adhikaraṇa*) and ‘abode’ (*āśraya*).

3 Substance

The realism of the entire Nyāya-Vaiśeṣika system is rooted in the category of substance (*dravya*). It is the one category that comprises a plurality of independently existing individuals. Some of the others are dependent on substance as their substrate (quality, motion, ultimate particularity), some are dependent on cognition (universal, particularity), and inherence is a relation of other categories. Unlike a number of the categories, for which a variety of terms have been attempted as translations, *dravya* has been rendered virtually without exception as ‘substance’, from the Latin translation for the first of Aristotle’s categories. Beyond its technical usage in Vaiśeṣika, *dravya* can mean in Sanskrit any thing or object, a material or ingredient, thus medicine, also wealth or money, or, more broadly, any object of possession.

Substance is the basic stuff of which all things material and immaterial are made; it is the ultimate possessor. The inherence relation of containment manifests the ontological priority of substance. Qualities, actions, universals and particularities exist only as contained in something else. Substance is also self-productive, meaning that only substances can cause the existence of other substances. Conversely, substances can be contained only in other substances. When a substance comes into being, it is produced from the unification of previously existing substances, as when two clay halves are joined to form a pot. The pot is said to inhere in the halves; the parts contain the whole. The parts of a substance can of course be contained in simpler parts, but because this chain of containment cannot continue *ad infinitum*, there must be simplest substances. Since a substance exists as contained by being produced from other substances and the simplest atoms are contained in nothing simpler, the latter are eternal. Composite substances are dependent and transient, ultimate atoms independent and permanent.

Since impermanent substances arise through the physical union of prior substances, only material substances can become and pass away. Physical substances have an eternal form as well: atoms of earth, water, fire and air are many and indestructible. The material atoms are, in a sense, contained in something other, although this is not considered inherence. Ether, space and time are three substances that are said to be one, not many, eternal, all-pervasive and a receptacle for corporeal things. The soul or self (*ātman*), of which there are many, is immaterial and therefore eternal. Mind, countless atoms of which populate the world, is distinct from soul. It is understood as an unconscious instrument that transmits perception to the soul. Since this occurs through contact and mind possesses action (motion), it is said to be material, although it never combines to produce composite substances as the other physical substances do; it is material but not ‘tangible’. Mind possesses qualities, such as number, dimension and separateness, which are attributed to both material and immaterial substances, but Praśastapāda also gives it priority and posteriority, which are elsewhere said to inhere only in material substances, as well as ability, which is otherwise thought to inhere only in immaterial substances.

Not only mind, but the other kinds of substance are distinguished from one another by the qualities that can inhere in them. Consciousness and other mental attributes are not identical to soul, but are qualities that the soul can possess. The physical substances together with ether are distinguished in that each is the receptacle for a particular kind of quality, associated with a particular sense. Earth is the substrate for smell, water for taste and natural fluidity, fire for colour, air for touch, and ether for sound. Where a quality is associated with a specific substance, it is the mark (*lakṣaṇa*) of that substance. The mark is a cognitive mark, allowing us to recognize substances, but is not an essence (*svarūpa*) identical with the nature of the substance (see §9).

Although ultimate, eternal substances are the only truly independent individuals, all instances of every category are interpreted as real, separate entities, even if dependent. Even nonexistences are entities, though having no positive nature of their own. Caused substances are wholes, born with the conjunction of the substances that make up their parts. (The parts, not the conjunction, are interpreted as the cause of the whole; see §7.) Despite the dependence on its parts, the whole is no less an entity unto itself than are its parts, the parts of its parts, or the ultimate atoms. Just as every quality or action in a substance is logically separable and unique, and therefore a real entity, so too are composite substances real individuals.

Against the traditions that hold the phenomenal world to be an illusory manifestation of a nondual transcendent reality, Vaiśeṣika ontology sides with theories of causality called *asatkāryavāda*, which deny the pre-existence of an effect in its cause (see Causation, Indian theories of §§1, 5). Each caused thing is a new thing. In this, there is agreement with the Buddhist schools, the major philosophical opponents of the classical Nyāya-Vaiśeṣika thinkers. They clash where the Buddhists assign the novelty of all effects to the momentariness of all existence, while a system of ontological categories like the Vaiśeṣika system is a means to justify permanent identity of individual entities through time (see Momentariness, Buddhist doctrine of). Substances, taken as substrates of qualities and other categories, permit an explanation of how a thing can remain one identical individual while undergoing change. A rock rolls down a hill, but is the same rock; the motion inheres in the rock but is not identical to it. A soul can acquire knowledge it did not always have or experience coming and passing pleasures and pains, all while remaining the same individual.

Nevertheless, the permanence of individuals must be qualified. Nothing exists if not in a substance, and this substrate of all that really exists exists either as an atom or as a unity composed of atoms. The atoms are uncreated and indestructible, but any change in the composition of a caused substance produces a new substance. If a clay pot is chipped, or even if a few molecules are brushed from its surface, the substance that was the original pot is destroyed as surely as if smashed with a sledgehammer.

This is reflected in the Vaiśeṣika treatment of particularity or individuality. Individuality is the category designating what distinguishes individuals as separate entities. It inheres in substance, yet does not inhere in any composite substance such as ‘this sherd’. A pure and simple individuality can reside only in an ultimate substance, an atom. It is not needed to verify the separate existence of a composite substance, or a quality or action, because the individuality of a whole and of an attribute is demonstrated by containment in a substrate, and therefore by the relation of inherence. At the lowest level, however, a substance can inhere in nothing. Here, indeed, individuality is an indispensable concept. For atoms and other eternal substances are the necessary building blocks of the individuality of all other things. As the ultimate abodes of individuality, the atoms must be distinct from all they contain. Therefore, no attribute of an atom can serve to show what it is as distinct from the next atom. As ultimate, the atoms are a plurality of indistinguishables, unable to be distinguished by themselves, but only by the necessary inherence of individualities.

The attempt to identify substance leads Nyāya-Vaiśeṣika into a dilemma. Pure independence is what it is to be real. An individual quality or an action is one because it is in a substance; substances that are whole are one, because the parts they are in are substances; the smallest parts, the atomic substances, are one because they are independent from all else. As has been seen, this adds up to the ontological priority of eternal substances, given that to be is to be a separable individual. But by the same token it becomes very difficult to state what a given atom is - it cannot be identified with any of its predicates, for it is their substrate and an individual distinct from them - and therefore difficult to say how the given atom is in itself distinct from the next given atom. What is the substance apart from what it has? There seems to be no way to say, and yet there must be if knowledge as distinct from error is knowledge of the real. Consequently some thinkers in the Nyāya-Vaiśeṣika tradition are led to posit obscure ways of directly perceiving a substance apart from whatever inheres in it. The cow barely visible in the shadows at night yet distinctly a cow is said to be a perception of the substance by itself, because its attributes, specifically its true colour, are not perceived. Such arguments, unsurprisingly, were ridiculed by rival schools. In the same vein, Śrīdhara affirms that yogins of developed skill directly intuit individual atoms. If the positive determination of individuals as separate is tenuous at best, one is left with distinguishing entities negatively by reference to relations with other individuals. As Nyāya-Vaiśeṣika thought develops, negative relations take a place of increasing importance (see §10).

4 Qualities and their inherence in substance

Quality (*guṇa*) and action or motion (*karman*) are the two categories in addition to substance that are considered objects (*artha*). Praśastapāda also expresses this by saying that ‘beingness’ applies to all categories, but ‘being’ as a general term only to substance, quality and motion, while the remaining three have ‘self-being’, their being in themselves (*svabhāva*; at Praśastapāda’s time, nonexistence was not yet an acknowledged category).

Like actions, qualities exist as individual realities, not independently but inhering in substances. Some are causes of other qualities and each contains the universal ‘qualityness’. The number of qualities specifically listed varies

slightly in different texts. Praśastapāda lists those occurring in material substances as colour, taste, smell, touch, priority, posteriority, gravity, fluidity, viscidity and speed. Ten qualities inhere in immaterial substances only: intellect, pleasure, pain, desire, aversion, effort, virtue, vice, ability and sound. Those remaining occur in both: number, dimension, separateness, conjunction and disjunction.

A number of the qualities are commonly called aids to perception. Though not identical to substance or the essence of substance, the qualities allow us to distinguish substances as separate kinds and as separate individuals (see §§3, 9). Qualities (as well as actions) have another important function with respect to the discernment of individual entities: they allow us to identify real and enduring individuals. Substances can change with respect to quality or action and yet remain the same substance. This was a central aspect of Aristotle's categories: substance provided a means to explain stability within change. The degree to which the Vaiśeṣika categories provide this is, however, in comparison with Aristotle, severely limited. The restrictions on identity through change are evident in the ways qualities act as causes and appear as effects.

Certain qualities are uncaused. These are the qualities that are 'marks', such as the smell of earth, which are coeval with permanent substance. Caused qualities are produced in one of five ways: by antecedents like qualities, conjunction, disjunction, action or by 'cooking' (*pācaka*), which is defined as hot touch or contact with fire. Action causes the qualities of conjunction, disjunction and speed. Conjunction and disjunction are among the several qualities (along with number and separateness when greater than one) that are relations and are therefore said to inhere in more than one substance at a time, thus not actually distinguishing individuals. Disjunction is said to cause only sound and secondary disjunction.

Of the three remaining causal modes, conjunction in two forms accounts for identity of changing substance. A conjunction is the contact of substances, without those substances thereby forming one (although conjunction occurs wherever a composite substance is produced). As a cause of qualities, conjunction other than cooking (cooking being conjunction of fire with another substance) is primarily associated with the immaterial qualities, that is to say, the attributes of soul. Understanding, pleasure, pain and other mental qualities can come to be contained in the soul or leave the soul without altering the real identity of the individual soul.

Cooking is in fact a specific kind of conjunction. Praśastapāda does not give a list of qualities caused by cooking, as he does for the other species of qualitative cause. Yet it seems clear that cooking is efficacious wherever a material substance undergoes change of quality without being destroyed. Praśastapāda mentions cooking as a cause explicitly only in connection with one substance, earth. Whether other substances can undergo qualitative change by hot touch is left ambiguous. Also, while a change in the odour or taste of earth is mentioned as a possible effect of cooking, colour is the most frequent example. Thus, a clay jar fired is the same substance as the greenware, though its colour has been changed.

'Cooking' may strike the reader as odd, yet it has a crucial explanatory function in the categories. Each quality is one entity, just as much as each substance is one. Containment in the substance, however, guarantees the unity of the quality. Whenever there is a change in the underlying substance, a new and distinct quality is born, and, apart from the few instances of 'cooking', any change in quality is a change in underlying substance (see §6).

5 Action

Action (*karman*, also translated 'motion'), the third category and the last recognized as an 'object', is significant in the causal mechanism of conjunctions and disjunctions, two qualities that, in turn, are central in the explanation of qualitative change. The actions are attributes that exist only momentarily and only in material substances. Divided into five kinds - throwing upwards, throwing downwards, contraction, expansion and motion (*gamana*, also translated 'going') - actions may arise from gravity, fluidity, conjunction or effort. The first three qualities productive of actions all reside in material substances. The quality of effort, volitional dispositions of the soul, establishes the link of action with consciousness. The category nevertheless does not overlap fully with a usual notion of agency, being always rooted in material reality. Thus all action occurs as some kind of physical motion. The divisions within this category were always a subject of debate even within the Nyāya-Vaiśeṣika tradition. If all actions are movements of material substances, then why not take the first four simply as various instances of the fifth, motion? Each of the two pairs of opposites is, unlike motion, associated with a definite direction. It was also asserted that these directed actions may be produced by conscious effort, unlike motion, which may occur in

the absence of consciousness. Thus the kinds of action serve to distinguish intentionally caused movement from blind events.

Just as the list of actions was disputed, so too was the status of action as a category distinct from quality (notably by Raghunātha in the sixteenth century). In fact the category of action furnishes the basis for the changing object. Although not all qualities are permanent or coeval with their substrates (some change while the underlying substance retains identity), all are nevertheless static. In the firing of a clay jar, one colour replaces another. When conjunction, a quality closely associated with actions, occurs, it is one unitary object that inheres in two substances. Action, on the other hand, is dynamic, and, while inhering in substances just like qualities, is momentary. Unlike qualities, which can produce other qualities, an action never produces another action. So in a chain reaction of ricocheting balls, to take an example, a conjunction of two substances produces an action, which terminates when the next contact is made, which conjunction in turn produces another action, and so forth.

6 Universal and particularity

The universal (*sāmānya*) and particularity (*viśeṣa*, also translated 'individuator' or 'describer') inhere in other entities and allow us to group and distinguish them. A quality is distinguished in name from a universal by the addition of an abstract suffix to designate the universal. 'Red' is a quality, but 'redness' is a universal. The strict separation of qualities and motions from the substances that contain them makes universals indispensable. Qualities and actions are individual - the red contained in one substance is by its inherence a separate thing from the red contained in another - and consequently qualities (as well as actions and substances) cannot be grouped or related in virtue of what they are in themselves. It is another side of the dilemma with substance: it is something other than its attributes, yet it is not possible to state what it is other than its attributes.

This dilemma is the threat of nominalism, and to some extent the two categories of universal and particularity ward off nominalistic objections to the realism of the categories. Such objections arose in the extensive debates with Buddhist thinkers, who argued that all universals were mental constructs at most (see Nominalism, Buddhist doctrine of). The Buddhist claim in fact does not appear incompatible with the ambiguous assertion of the *Vaiśeṣikasūtra* that both universal and particularity are 'with regard to the understanding' (*buddhyapekṣa*). Later commentaries said that the universal is the cause of the cognition of inclusion, and the particularity the cause of the cognition of difference, while insisting that these categories, like the others, are real in themselves, not a mental product.

The universal may be defined as that which inheres in a plurality of objects and brings about the idea of itself in any one. The universal pervades all its objects, having the same form in all in which it inheres. In this it is distinct from qualities. Thus the blue of a blue substance is one individual, coextensive with and momentarily posterior to its underlying substrate. (The quality is produced momentarily after the substance is produced, since it is caused by the substance; to make it simultaneous would risk rendering the quality and substance identical.) It inheres in only one thing, and is itself the locus of inherence. The universal blueness, however, as opposed to the quality blue, inheres as one in the many distinct and individual qualities that are all correctly called blue. The inclusiveness of the universal is said to distinguish it from its substrate. Thus, for example, substanceness is not identical with substance, since the latter is known by exclusion, by reference to what it is not. A further conclusion drawn is the eternality of universals, since, as independent from their substrates, universals are not produced by their substrates and so do not go out of existence with the destruction of the substrate.

Unlike the quality that it is in, nothing is in the universal. Since it is not a locus of inherence, the universal (like the particularity and the category of inherence) is not an object. Even with the commitment to the reality of universals, there is a sense in which they do not exist. One reason for this is a regress problem. The most general of universals, being, inheres in all objects, that is to say in all substances, qualities and actions. If 'being' were to inhere in universals as well, and universals could therefore be substrates of inherence, then 'being' itself would be an object, requiring a yet more general kind of 'being' to inhere in it, and so forth *ad infinitum*.

Universals not only allow us to include, but also to distinguish. 'Blueness' makes it possible to group all blue entities as one in respect of colour, but it also distinguishes from other colours. For this reason the universals are divided into 'higher' and 'lower'. Of the higher there is only one, 'being', since it is the only universal that is purely inclusive, all objects being its substrates. All other universals allow discrimination, and so cause both the

cognition of inclusion as well as the cognition of particularity. All universals more specific than ‘being’ are therefore called ‘particular universals’ (*sāmānyaviśeṣa*). Any cognition that involves inclusion due to similarity of form, however, is properly called a universal, not a particularity.

Particularities, the cause of the cognition of distinction, like universals inhere eternally in substrates without themselves being inhered in. Unlike universals, however, each particularity inheres in only one substrate. Since they are eternal, and since they have only one substrate, that substrate can only be an eternal substance: atoms, ether, time, space, soul or mind. The atomic substances are characterized by nothing in themselves that allows their discrimination, and therefore particularity is ascribed as the cause of knowing atoms to be distinct, a distinction perceptible to the yogin alone.

Despite the seemingly unclear ontological status of universal and particularity, they are crucial concepts in the Vaiśeṣika system of categories. As has been seen, there is nothing about a substance itself, which is presented as a bare receptacle, a harbour for attributes, to allow us to say what the substances, the foundations of reality, are in themselves. This function falls largely to these categories, and is defended on the grounds that, apart from the reality of universals, there would be no unity of individuals, and consequently no object denoted by words, which would entail the vacuity of all categories.

7 Inherence

Inherence, perhaps the least accessible of the categories, is nevertheless essential both to the organization of the Nyāya-Vaiśeṣika categories and to the ontological priority of substance. This category represents a special kind of relation. It is the permanent and indissoluble connection of two entities which are knowably distinct. The relation of inherence also indicates an order of dependence, being a relation of container to contained. In virtue of the permanence and the order, inherence is distinguished from the other kinds of relation, the pair ‘conjunction’ and ‘disjunction’, which are classified as qualities.

The categories could be (and to a large extent are by the eleventh-century philosopher Udayana) defined simply in terms of inherence relations. Substance can inhere in substance, and is inhered in by qualities, actions and universals. Eternal substances are distinguished because they are also inhered in by a particularity. Qualities inhere in substances and have qualityness inhering in them; actions inhere in one substance at a time and have actionness inhering in them. Universals inhere in a plurality of entities but have nothing inhering in them. Likewise, nothing inheres in particularities, which, however, inhere in only a single substance. The relation inherence itself inheres in nothing and has nothing inhering in it.

In the order of inherence relations among the categories, the contained provides unity and identity, the container the reality of the single individual entity. Universals are not themselves objects, but are contained in objects of all sorts, actions, qualities and substances; actions and qualities are objects, but always contained in substances; substances, if contained at all, are contained in another substance. The nesting of contained and container comes to an end with the atomic, eternal substances.

The category of substance provides the foundation for the Nyāya-Vaiśeṣika quest for permanence and self-sameness, the continuity underlying all change. A quality must be a quality of something, an action must have an agent, and a word, to have meaning, must refer to something.

The inherence of substance in substance is always a whole-part relation, the whole inhering in the parts. As the whole is itself a unitary substance, the relation implies that the whole is something more than the aggregate of its parts. In support of this contention, the inherence of substance in substance is considered a special case of causality. The whole inheres in the parts and the parts are the inherence cause of the whole. The cloth inheres in the threads and the threads are the inherence cause of the cloth. The inherence of cloth in threads is not the same as the conjunction of the woven threads, on the grounds that conjunction, a temporary relation, occurs when action joins two previously separately existing substances, whereas the cloth, as contained, cannot exist separately from the threads. Thus, an aggregate of material substances does not make the whole aggregate one substance, but the inherence of the whole in the parts does. The clay pot is one substance, a whole that inheres in its parts, other substances, ultimately earth atoms; but two pots touching remain a distinct pair. A living organism is one substance made of innumerable substances, yet remains distinct from the ground it stands on. Classical Vaiśeṣika says little beyond distinguishing inherence from conjunction to maintain that wholes are other than aggregates.

Other contentions make the distinction difficult to uphold, as the slightest change in a composite substance, brushing a few molecules off the pot surface, transforms it into an entirely different whole, an utterly new substance. Inherence, while rendering substances the foundation of a pluralistic realism as the containers that are not contained, also obscures what the individual unity of the substances consists in.

8 Parallels to the relation of inherence

It is instructive to compare the relation of inherence with a partial analogue in Aristotle's *Categories*. The analysis of predication shows for Aristotle a relation of containment that points to an ultimate substratum. A universal term, such as 'horse', can act both as subject and predicate in a sentence. But 'this horse', the term denoting an individual animal, can function only as subject. Grammatically, it is an ultimate subject of predication, and indicates a substance. Entities, which are denoted with words, may be said of something, present in something, both said of and present in, or neither said of nor present in. The term 'this horse' is an example of the last, and therefore indicates a substance, which, in the strictest sense, can neither be said of nor is present in anything else.

A tool for analysis, these relations do not constitute separate categories for Aristotle, unlike the Vaiśeṣika category of inherence. Moreover, in early Nyāya-Vaiśeṣika there is nothing analogous to the Aristotelian 'said of' relation. The difference is revealing for understanding the structure and organization of the Vaiśeṣika categories. Members of the Aristotelian category 'quality' (of which Aristotle gives no definitive listing) can be both 'said of' and 'present in', although not in the same sense. In the universal statement 'Roses are red', the quality 'red' is said of the subject 'rose' and the quality is real (for other red substances exist) even though the red rose in my vase withers and turns brown. But it may also be said that the rose in my hand is red in the sense that red is 'present in' it, meaning a particular red, a red that is no longer when a petal falls. Aristotle asserts the universality of qualities along with their dependence on ontologically fundamental substance: red exists without this red thing, but not without red things; and this red does not exist apart from this red thing.

The manner in which a quality may be conceived as present in a substance in Aristotle is analogous to the Vaiśeṣika understanding of qualities, which are in all cases individual and coextensive with the substances in which they inhere. Thus the Vaiśeṣika literature goes to lengths to defend the reality of a colour such as 'variegated'. Where a composite material substance does not have one single shade throughout (the fabric of a Hawaiian shirt, for example), its colour must nevertheless be one. The quality is one not by being what it is, but by being contained. Consequently any change in quality - with the exception of the cases distinguished as qualitative change due to 'cooking' (see §4) - is due to an underlying change in the containing substance. In Aristotle, where one petal falls the rose still is, although altered, and that particular red is no more; in Vaiśeṣika, both the substance itself and its qualities have been succeeded by new entities.

Therefore it might be said that in the Vaiśeṣika categories the identity of form is a separate consideration from the unity of an individual. This also marks a telling difference from Aristotelian ontology, where the individual substance is not only one as a substrate, but is one because it is a 'this', an essence. (Although some of the Vaiśeṣika substances are distinguished by qualities peculiar to that kind, this 'mark' is never the equivalent of the Greek notion of essence.) Nothing in classical Vaiśeṣika is analogous to the Aristotelian notion of a quality being said of, not present in, a substance. Vaiśeṣika does acknowledge a real unity of form to qualities of different individuals. This must be explicable by means of the inherence relation, and thus the universals, such as substanceness, qualityness, redness, are recognized as a distinct category. These too are present by containment. Redness inheres, not in substances, but in the reds, which in turn inhere in substances. When a person smells the rose, inhaling pollen in the process, the original composite substance has been destroyed and replaced by a new one, yet we will continue, correctly, to call it a rose.

9 Later developments to inherence and relations

Where Aristotle grounded the individuality of substances in an essence, which led him to wrestle in the *Metaphysics* with maintaining the ontological priority of substance to form, the Nyāya-Vaiśeṣika categories were careful to keep substance separate from quality and universal. This led to another philosophical difficulty, the difficulty of saying what a substance in itself is, to give content to the assertion that a substance apart from all other categories has a *svarūpa*, a nature in itself. We have seen this in a couple of respects. It is difficult to justify the distinction of a whole from an aggregate. And the ultimate substances are reduced to bare particulars, atoms,

which in themselves cannot be distinguished, requiring the introduction of particularity as a category. The term *svarūpa*, self-nature, was often connected more closely with the discussion of universals as they qualify substances, not the substances in themselves.

Navya-Nyāya, in the Nyāya-Vaiśeṣika tradition the 'new' school inspired by Udayana and beginning with Gaōgeśa (fourteenth century), significantly expands the analysis of relations, in general associating relations more intimately with the relata. Thus inherence was traditionally asserted to be one, on the grounds that it is always the same relation, a permanent relation of contained to container. This item of doctrine becomes a matter of debate, with some asserting that inherences are many and equal in number to the pairs of entities related by inherence.

The kinds of relation were also rethought. In the earlier period, relations were explained primarily by inherence, a separate category, as well as conjunction and disjunction, which are qualities. Navya-Nyāya, holding that the individual may also be related to other entities by its own nature, locates some relations not in separate categories, but in the individuals. This *svarūpasambandha* ('self-linking connector', 'peculiar relation') comes to have many varieties, but is especially important as the relation between a particular universal, that is, a universal less abstract than 'being' that therefore distinguishes what it qualifies from other things, and the entity the universal qualifies. For Praśastapāda, short of yogic knowledge of a substance as its very self, the knowledge of substances and other individuals is had by perception of an individual's own nature (*svarūpa*), which is the perception of a particular universal (*sāmānyaviśeṣa*) inhering in the individual. In Navya-Nyāya, the universal form, while still of a different category from the individual it qualifies, is more closely associated with the individual by making the relation of redness to red and of Bobness to Bob not inherence but *svarūpasambandha*. The form is still separate, but its relation to the individual is located in the individual itself, no longer in a third category. In the face of ultimate substances, bare and seemingly indefinable particulars, the particular relation marks an attempt to make definition possible by a more elaborate mechanism of specifying a substrate's relation to other entities.

The other major use of the *svarūpasambandha* relation is in explaining negations, in the relation of a substrate to something nonexistent, as in the proposition 'There is no pot on the mat'. This relation involves the final category.

10 Nonexistence or absence

The seventh category is of later origin than the first six. Discussed in the *Vaiśeṣikasūtra*, although not classified as a category, it is given little attention by Praśastapāda. It is acknowledged as a separate category by later writers and accepted without question in the subsequent Navya-Nyāya tradition. With the acceptance of nonexistence as a category, the structure of the categories is threefold. Substance, quality and action are all *satta*, reality, the name of the highest universal, and are all designated objects. The first three as well as universal, particularity and inherence are all designated *bhāva*, real, existing or present, in distinction to the seventh, *abhāva*, nonexistence or absence. Analysis of negation comes to be a central concern of Navya-Nyāya, including such questions as whether an absence is perceptible and whether the absence of an absence is positive or negative, that is, whether it is itself an absence. The basic division of nonexistence or absence was into four: prior absence is the nonexistence of an entity before it has been produced, posterior absence is its nonexistence after destruction, absolute absence is its nonexistence at all times and mutual absence is the nonexistence of one thing in another, such as the mutual absence of fire in water. The assertion of a mutual absence is equivalent to an assertion of nonidentity.

Any assertion of nonexistence is taken as an implicit reference to some positive entity, called the *pratiyogi* (counterpositive), which could be present in a substrate. Ultimate atomic substances appeared in themselves to be bare receptacles. Even with the addition of particular relations grounded in the individual substrate, to say something about an entity in itself is to say something about its relation to something else. Consequently a negative statement demands that the absence be a distinct entity, even though having no *svarūpa*, no nature of its own. 'There is no pot on the mat' is an assertion that, like any other assertion about the mat, places the mat in relation to something other, namely an absence (see Negative facts in classical Indian philosophy).

11 The nature of the self

A theory of categories is intended to lay out the structure of reality, affording knowledge of what is. For philosophy in India, a person seeks knowledge of what is, not to satisfy human curiosity, but to fulfil the highest

possible goal, commonly described as liberation of the soul. Traditionally, philosophical knowledge is one means to that end. The realism of the categories yields at the same time an account of that highest state of soul.

Part of that account, much disputed by other schools of thought, is the reality of soul (rejected by the Buddhists) and the plurality of individual souls (rejected by most other major schools). While material substances are defined and their existence is inferred by their attributes, it is still argued that perception of material substances themselves as distinct from all inhering qualities is possible. The establishment of the soul is more problematic, because it is asserted from the outset that the soul is an imperceptible substance. Therefore it is knowable only by inference. The existence of the self is inferred primarily from perception and agency. There must be a perceiver to whom the perception belongs, an agent who acts. Beyond this argument, the soul is inferred on the basis of the understanding of the nature of qualities: since no quality is independent - all exist only inhering in a substance that can contain them - and since we perceive certain qualities that are not encountered in material substances, namely, cognition, pleasure, pain and so forth, the self must exist as their substrate. There are no marks of soul in the sense that smell is the mark of earth. Certain qualities can exist in soul alone - pleasure, cognition and others - and all can also be absent. No qualities are coeval with soul. More clearly than for any other substance, soul is a container, not identifiable with and separate from any of its contents. To seek out and grasp the structure of reality is therefore to grasp the self. Liberation is ‘the subsistence of the self in its own pristine condition, marked by the cessation of all the specific qualities pertaining to it’ (Śrīdhara, *Nyāyakandalī*, to *Padārthadharmasaōgraha* VI, x; trans. G. Jha, 1915). Paradoxically, the simple picture drawn of the soul epitomizes the entire system of categories in its intricate complexity.

Opera, aesthetics of

Opera, which may be defined as a dramatic action set in large part to music, is an inherently unstable art form, more so than any other. It has been characteristic of its practitioners and critics to call it periodically to order, in idioms which vary but carry much the same message: the music exists to further the drama. This has often been taken to be a matter of settling the priority of two elements: music and text. But in fact three are involved: music, text and plot (or action).

Opera began very abruptly in Northern Italy at the end of the sixteenth century, partly as the result of discussions about its possibility. To begin with, familiar Greek myths were employed, set in the vernacular, with simple accompaniments so that every word could be heard. This led to pre-eminence for the singers and for spectacle. After each wave of excess - vocal prowess, dance interludes, stilted plots and texts, then once again, in the nineteenth century, empty display, and later gargantuan orchestras - there was a movement of revolt. Philosophers rarely took part in these aesthetic disputes, most of them being uninterested in music, and possibly more relevantly, being uninterested in any subject which can only be studied in historical terms. But it is fruitless to think about opera apart from its manifestations; every great operatic composer makes his own treaty between the potentially warring elements, Wagner being the most passionate propagandist for his own conception. In the twentieth century the aesthetics of opera have become pluralistic, as has, to an unprecedented degree, the form itself. The perpetual danger is that opera should degenerate into entertainment, and it is always the same message that recalls it to its original function - one which most spectators and listeners are happy to ignore: opera is a form of drama.

1 The constituents of opera, and a promising beginning

An opera is a drama which is in large part sung and is accompanied by an orchestra. Hence one can see that it is not an art form in which the elements are likely to remain in a stable relationship. The history of theorizing about opera, which naturally runs alongside the history of opera itself, is one of constant complaint and propaganda for a return to the ideals of the founders of the form - though as musical and other means develop, it is taken for granted that they will be realized in different idioms.

Although drama with musical accompaniment was no new thing when the theorists of opera were holding their debates in Florence towards the end of the sixteenth century, it had never been discussed in a systematic way. The Florentine theorists wished to return to something approaching the original performance-conditions of Greek tragedy; they were typical of Renaissance propagandists, both in seeking a validation for their theories by claiming that they were a return to antiquity and in having only a vague idea of what that would be. The Camerata, as they called themselves, were in fact concerned to bring a new art form into existence in the light of the possibilities of staging large-scale spectacles at North Italian courts - an art form in which actors with fine singing voices could perform versions of classical myths with whatever instrumental forces happened to be available. It may well be the only major kind of art for which an agenda has been worked out in advance of any actual examples.

As a notoriously liquid language, Italian possessed an in-built possibility of lyricism which was lavishly exploited by the first great master of opera, Monteverdi (1567-1643), whose *Orfeo* got the form off to a remarkably impressive start. It is sparsely accompanied, so that every word can be clearly understood. The elements of opera - singing, orchestral music, text and drama - are in the accord that the Camerata had promulgated. Most of Monteverdi’s subsequent operas are lost, but his last two, dating from the early 1640s, survive; though they are both different from *Orfeo*, and from one another, they maintain the principles and thus the balance which he had exemplified from the beginning. But having begun as a court entertainment, opera rapidly became one that appealed to the masses. It would be absurd to maintain that its popularity led to its decline. That would probably have occurred in any case, but what took over were an ever-greater lavishness in stage spectacle, longer and less relevant dance interludes, and a tendency on the part of the vocal soloists to demonstrate their often prodigious technique. Within a century of its birth, opera had already become decadent.

2 Aesthetics and history

The aesthetics of any art form, if they are to serve any useful purpose, are necessarily closely linked to the form’s

history; this is especially the case with the performing arts. The great manifestos which punctuate opera's history have all been devoted to the same task: that of recalling opera to the high ideals with which it began, and analysing the factors which have led to its departure from them. How large, for example, can the orchestra become without rendering the words that the singers are producing incomprehensible or even inaudible? How can one hope to understand a singer who produces an elaborate sequence of notes on a single syllable? The old tug of war between pleasure and instruction is nowhere more acute than in opera, instruction favouring simplicity of means, pleasure various kinds of display. Many of opera's greatest practitioners and all its leading theorists have been people who conceived of it as playing an important role in society, and of performances of significant works as serving to unite the audience in a celebration of shared communal values. But the temptations to indulge in one or another mode of virtuosity have repeatedly proved too strong.

A more deep-seated reason for the instability of opera lies in its relationship with the purely instrumental music of its time. For its earliest practitioners this was hardly a problem, since instrumental music as such was not yet a going concern. There is nothing inMonteverdi's operas that we can recognize as large-scale musical organization. Music remains subordinate to drama to a degree which ears familiar with Mozart orWagner can find frustrating. But, in the eighteenth century, before purely instrumental music was fully under way as an autonomous art, composers of opera were developing the aria, in which a character who was previously getting through a lot of musical prose, as it may be termed, takes their time to explore an emotion at greater length, to a melody which is appropriate to that emotion. The effect of this was to hold up the action, so that opera tended, in its second century, to become increasingly static.

This stalemate could not be broken until instrumental music became much more diverse in its modes of organization than it had been before the birth of sonata form, in the latter part of the eighteenth century. However much discussion of opera there might have been, it could not attain an adequate degree of detail and sophistication until music itself had advanced beyond a dependence on dance forms and counterpoint. For debate about the relationship between text, drama and music depends on what are envisaged as the possibilities of music. The expression of conflicting emotions only becomes feasible when contrasting themes are brought into relationship with one another and their conflicts are resolved in terms of more or less large-scale harmonic organization. That is what happened in the sonatas, symphonies and chamber works ofHaydn and Mozart, and what therefore enabled Mozart to write his operatic masterpieces, which dwarf all those that preceded him. By contrast Gluck (1714-87), the co-author of the Preface to his opera *Alceste*, one of the most famous of all insistences on the primacy of drama, gives the impression of advance in his 'reform operas' only by returning, in his own way, to a pre-Handelian simplicity. He made a virtue of necessity by avoiding all musical elaboration, thus conveying a unique sense of directness and dramatic relevance.

3 Mozart: sublime complexity

Mozart (1756-91) is the only great composer who is equally distinguished in operatic and instrumental works. His greatness in each fed that in the other. He had no need to theorize about opera, because he was able to take over into his operas the procedures that he employed above all in his sublime series of piano concertos. In his mature operatic masterpieces the glories, above all, are the huge ensembles. Though, strictly speaking, they are not in sonata form, they give the listener the firmest sense of a musical argument which underpins and indeed absorbs into itself the text and action, creating a seamless whole.

It is perhaps these works, more than any others, which led Joseph Kerman, in his influential *Opera as Drama* (1956), to claim that, in relation to opera, music serves the same function that poetry serves in poetic drama; above all in Shakespeare. That cannot be quite right. If one wishes, one can read libretti by themselves (not recommended). But one cannot read Shakespeare's plays without the poetry. The most one can do along those lines is paraphrase it. Shakespeare does his thinking in the language which he commits to paper. But in opera, even when the librettist and the composer are the same person, there are the words and there is the music, and one can admire or deplore the setting of the former to the latter. What precisely follows from this it is hard to say. Certainly the effect in the finest of operas is one of indissolubility. But there remains a crucial difference between the intensification of effect which music can achieve, and the absolutely singular effect of poetic drama. That is one reason why there is so much more criticism of poetic drama than of opera.Mozart's Don Giovanni is perhaps as complex a figure as Shakespeare's Hamlet, but though there are vast amounts of commentary on both these

characters, that on Hamlet will always far outstrip that on the Don. Poetry seems to challenge us to explain its implications, since if it is as great asShakespeare's we will never complete the task. Music, at least when it functions as it does in Mozart's operas, deepens a meaning which the text and action provide, and can add ambiguities and complexities, but within more circumscribed limits, it seems. Thus even in the case of a work as fascinating in its levels of operation as *Così fan tutte*, there is always the text to refer to, and the text is rather straightforward. In one way, the music itself provides most of the criticism of the drama that we need, at the same time as it creates it.

4 The trauma of Wagner

As with nearly all supreme creative figures, Mozart was both an inspiration and a depressant to his successors. In the presence of his works, discussion of the aesthetics of opera seems superfluous. But once more, degeneration set in, and once more in Italy, the home of opera. The writers of so-called *bel canto* opera were largely unconcerned with theory, and in any case the culture industry of which they were a part gave them no time for anything but the composition of their next work. But it was the dominance of singers which again led to drama yielding to music. Meanwhile, in Paris, the demand for lavish spectacle reached a new pitch of vulgarity, perfectly catered for by the white elephants of Meyerbeer (1791-1864). 'Effects without causes' was Wagner's description of his operas. It is Wagner (1813-83) who provided the next set of fundamental arguments about the nature and function of opera. Having himself set off on a course which was internationally influenced, with Meyerbeer as one of the contributors to his development, he was led by a series of historical events (many of which were unconnected with his art) to think with a depth and sustained energy about opera which has no parallel in the history of any of the arts, and which has set the agenda for operatic aesthetics ever since.

Wagner's dissatisfaction with opera was part of a wider revulsion from the whole society in which he lived. As a participant in the Dresden uprising of 1848-9 he was impelled both to think through the whole set of relations between politics and art, and to develop the concept of a total work of art, which would mirror the reintegration of man and society, and without which he could see only misery ahead. He saw in myth the fundamental truths about the human condition, but it was myth reinterpreted from a psychological standpoint. This could only be realized by the writing of libretti (he always wrote his own) of a complexity and density previously unknown, and the relegation to a subordinate place of music, which would nevertheless possess a degree of sophistication comparable to that of Beethoven's instrumental works. The aim was something far more ambitious than any operatic composer, indeed any artist, had entertained before: the transformation of consciousness by overwhelming communal experience.

The enormous body of theorizing whichWagner produced after the failure of the uprising is characterized by generalizations of Hegelian proportions, and expressed in language no less forbidding. But when he was introduced to the writings of Schopenhauer in 1854, he revised his views about the importance of music in relationship to the other elements of music drama, moving to a position where he saw it as the main conveyor of the drama. His celebrated later statement, that his dramas were 'deeds of music made manifest', sums up his new position. There has been an enormous amount of debate about the connections between Wagner's theories and his practice, but the overwhelming force of the latter and the ambitiousness of the former have guaranteed that his views and his art have been a major focus of aesthetic discussion, and not only of opera. Operatic theory and practice have been polarized, for the last 140 years, into pro- and anti-Wagnerian positions. The most strenuous objectors have been of two kinds: those who feel that his claims for art, and for music drama in particular, are preposterously inflated, and who have therefore advocated a return to some kind of pre-Wagnerian aesthetic (Stravinsky being the most articulate case); the second group have seen opera as an instrument of social change only on the condition that it stresses its own artificiality and leads its spectators to think about issues in a highly conscious way. Pre-eminent among this school have been the Marxists Brecht and Weill.

5 Aesthetic pluralism

Few general conclusions can be drawn from studying the history of opera and its commentators. Each operatic composer of genius has worked out the relationship between text, drama and music in his own way. Since operas which possess a fine text but contain no distinguished music do not survive, and some operas survive which possess a wretched plot and text but magnificent music, it is often claimed that opera is fundamentally a musical, not a dramatic form. The fact that one can enjoy an opera while having only a vague idea of what is being sung or

what the action is seems to point in the same direction. These claims leave open the view that the operas which matter most are those in which drama is articulated by music, and that those in which only the music counts are less artistically significant.

Operas are popular for different reasons, and many opera lovers, or fans, are more interested in hearing superb voices show off than in anything else. The distinction between entertainment and art seems to be more laxly applied here than in the case of most other art forms. The battle for opera as a serious form, which ranks at its best with the greatest art forms, is one that is constantly having to be re-fought; it can be no coincidence that it is always conducted in terms of opera as drama.

Operationalism

'Operationalism', coined by the physicist Percy W. Bridgman (1927), has come to designate a loosely connected body of similar but conflicting views about how scientific theories or concepts are connected to reality or observation via various measurement and other procedures. Examples of an operation would be the procedure of laying a standard yardstick along the edge of a surface to measure length or using psychometric tests to measure sexual orientation. In the 1920-50s different versions of operationalism were produced by, amongst others: Bridgman, who was concerned with the ontology of basic units in physics; behaviourists such as E.C. Tolman, S.S. Stevens, who were concerned with the measurement of intervening variables or hypothetical constructs not accessible to direct observation, as well as B.F. Skinner, who sought to eliminate such nonobservables; and positivistic philosophers of science who were analysing the meaning of terms in scientific language. Conflation of their different operationalist philosophies has led to a great deal of nonsense about operational definition, methodology of observation and experiment, and the meaning of scientific concepts. Operationalist doctrines were most influential in the social sciences, and today the primary legacy is the practice of operationally defining abstract social science concepts as measurable variables.

1 Bridgman

Nineteenth-century physics extended the scope of Newtonian mechanics to include radiant heat, sound, electricity and magnetism, and so on, by modelling these phenomena as waves through a rarefied fluid-like ether. The 1887 Michelson-Morely interferometer experiments failed to detect a suitable ether, thereby laying the basis for the replacement of Newtonian mechanics by relativity theory. P.W. Bridgman viewed the Einsteinian revolution as challenging the assumptions on which classical experimental physics was based, and thus saw special relativity theory as calling into question all absolute physical principles and the existence of absolute physical matter. What, then, could be the subject matter experimental physics studied? Perceiving Einstein as having built relativistic physics out of various basic or elementary operations such as were used to measure relative simultaneity, he concluded that these basic operations not only connected theory to experiment but themselves were what experimental science studied. The heart of Bridgman's operationalism thus was an ontological view about the basic constituents of empirical reality. When he said, 'we mean by any concept nothing more than a set of operations; the concept is synonymous with the corresponding set of operations' he was making the claim that concepts ultimately referred to constituent basic operations and nothing more. He thus rejected the idea that there were any *things* which the basic measurement procedures measured. In later works he embraced the incipient subjectivism of this position.

Bridgman insisted that each operation defines a separate concept, by which he meant that the referents of a given concept were precisely the mix of operations used in the specific operational definition. Critics charged that concepts like *temperature* admit of different measurement procedures, and so it was a mistake to equate the *meaning* of temperature with any particular procedure for measuring temperature. The extension of the term 'temperature' encompasses things measured by different procedures, but extension is not the sense of 'meaning' in Bridgman's dictum that the meaning of a concept is the set of operations; for his position denied the existence of things which could be the extension of a concept. Bridgman readily acknowledged that there could be connections among operationally defined concepts, and that terms like 'temperature' encompassed such connected operationally defined concepts. The basis of these connections was theory. For example, the various distinct concepts lumped under the rubric 'length' are 'connected' by the Lorentz transformation group from relativity theory - a kind of 'fusion' of concepts (see Relativity theory, philosophical significance of §1). Not all concepts in theories were definable by operations of physical measurement or experimental manipulation and design, and Bridgman allowed that 'paper and pencil' operations could be used to operationally define them.

For Bridgman operational analysis was a means for explicating and validating scientific concepts by disassembling theories and determining what was objective (rooted in basic operations). Non-objective theory content led to pseudo-problems. However, operational definition was not intended by Bridgman to be constitutive of concepts, a formula for doing science, the meaning link between formal and factual propositions, or a means of eliminating subjectivity from scientific knowledge. He increasingly found positivistic and behaviourist 'operationalist' philosophies that attempted to do so uncongenial. Although he had extended exchanges with operationalists like

Stevens and Skinner, these eventually led to total estrangement.

2 Logical positivism

Logical positivists, too, focused on the implications of the Einsteinian revolution: where Newtonian mechanics went wrong was postulation of the fictitious ether, which, referring to nothing, was said to be an empty or meaningless concept. Utilizing resources of the new symbolic logic they sought to develop a precise language for doing science in which concepts referring to fictitious entities were precluded. Things were ontologically real precisely if statements about them could be verified. In their reconstructed language for science, vocabulary terms were divided into the *logical*, the *observational* and the *theoretical*. Logical portions of language were reduced to symbolic logic and hence were tautological. Observational terms referred to directly experienceable things and so observation-language assertions were epistemically and ontologically non-problematic. Unrestricted introduction of theoretical terms led to the postulation of fictitious entities. To avoid this, legitimate theoretical terms had to be suitably defined by a 'dictionary' of 'correspondence rules' that gave observational content to theoretical assertions. Until correspondence rules are added, the only meanings theoretical terms have are those 'implicitly defined' by the formal connections in theoretical laws (see Theories, scientific §§1-2).

Initially the correspondence rules were required to be *explicit definitions* that reduced theoretical terms to abbreviations for complex observable conditions according to Schlick's dictum that the meaning of a statement is its method of verification (see Meaning and verification §2). Explicit definitions are stipulative definitions, hence analytic truths. Positivists assimilated Bridgman's dicta that the meaning of a concept is its corresponding set of operations and that each operational procedure is identified with a distinct concept to explicit definition since basic operations could be described using observation terms. Such conflation fundamentally distorts Bridgman's position. Positivistic operational definitions are describing procedures for measuring the very physical things Bridgman denied, and operational definitions are being put forward both as a method for doing science and as connecting the formal to the factual.

Later positivists came to see that some terms in theoretical physics could not be identified with observable conditions. Taking an increasingly realist position on theoretical terms they became concerned that, say, temperature could be measured via different operational procedures, so they loosened restrictions on admissible theoretical terms by admitting a plurality of *reduction sentences* which were operational procedures *partially defining* the terms by specifying observable meaning relative to a specific experimental context. Different operational definitions of the same term allowed for different procedures and contexts. Reduction sentences assert contingent relations between apparatus, theoretical entities, and their observable manifestation as the output of detectors or measuring devices. They are empirically true or false, and thus do not specify meaning analytically like stipulative explicit definitions. What connects the various correspondence rules partially defining 'temperature' is the contingent fact that all these temperature procedures are measuring the same physical *thing*.

Positivists continued to conflate their position with Bridgman's, now likening operational definitions to reduction sentences - which led them to criticize Bridgman's view that each operational procedure defined a distinct concept. They also criticized Bridgman for his growing emphasis on the subjectivity he saw growing out of the denial of any absolute physical reality and his view that the objectivity of science rested in what scientists *do* when they operationalize.

Later the positivists came to see that some terms (such as the Ψ function in quantum mechanics) could not be individually defined even by reduction sentences. This led to the weaker requirement that theoretical terms did not have to be individually operationally defined so long as they occurred essentially in the theory and the theory itself had observable consequences specified by an *interpretive system* of correspondence rules linking the theoretical and observational components. Positivists were never able satisfactorily to specify requirements for interpretive systems that demarcated scientific from nonscientific systems. Trading on earlier conflations, in moving to interpretive systems some positivists saw themselves as rejecting Bridgman's operationalism.

3 Behaviourisms

Although 'operationalism' was introduced to psychology around 1930, S.S. Stevens brought it to prominence. He argued that scientific disputes are rooted in disagreements over the application of concepts. Since the application

of concepts is rooted in concrete operations, agreement on the operations that should be associated with a concept would eliminate previously unresolvable disagreements. If there are disagreements in the application of a concept these can be resolved in an 'operational regress' in which applicability is settled by iterated appeal to less problematic concepts.

Operations consist in gross physical behaviours (say, laying a yardstick along a surface) and a result (number at the point of edge congruence). *Denoting* is the most fundamental behaviour on which all operations depend. *Results* are the outcomes of discrimination, which 'is the fundamental operation of all science'. Science thus depends on observer characteristics and so psychology becomes 'the propaedeutic science', providing data on which operational procedures depend. But psychology *qua* science itself must be operationalist.

Although operations rest in scientists' discriminatory capabilities, Stevens rejected any notion of a sensory given or subjective basis for science. Operations *are* behaviours and the basic operation is 'to react discriminatively'. Science thus is 'public'. Measurement scales are constructed out of complexes of operations which determine their arithmetical properties.

Around 1933-4, Stevens encountered Bridgman's operationalism and logical positivism, and in subsequent writings allied his independently developed 'operationalist' philosophy with their positions despite substantive disagreements over their reliance on subjective experience or the sensory given. It is unclear whether Stevens subscribed to the view that concepts are synonymous with their associated operations, but he was unsympathetic towards what he understood to be positivism's 'linguistic operationalism'.

E.C. Tolman pioneered an 'operationalist' approach to mental phenomena in the 1920s, although he did not adopt the term until 1936. Mentalistic concepts required external criteria of application. Behaviour is a complex function of stimulus conditions, hereditary makeup, past training and appetite or aversion. *Intervening variables* represent an organism's readiness to respond to stimuli and are to be operationally defined by means of standard experiments. One measures independent and dependent variables. Intervening variables are specified by holding all but one independent variable constant then determining the curve expressing the functional relationship between the selected independent and the dependent variable. Intervening variables thus required defining experiments. As Carnap was making the switch from explicit definitions to reduction sentences, Tolman spent some time in Vienna (1933-4), and his characterizations increasingly resembled Carnap's hypothetical constructs defined by reduction sentences. Whereas positivists viewed the operations linguistically, Tolman continued to construe them psychologically.

Stevens' articulation of the operationalist position provided focus for discussions of methodological issues surrounding behaviourism. Clark Hull (1940) had been an early advocate of the geometric method in psychology and quickly allied himself with axiomatic themes in positivism. Although he made little contribution to operationalism himself, his student Spence collaborated with the positivist Gustav Bergmann to produce a positivistic explicit definition version of operationalism (1941). B.F. Skinner was an early advocate of an explicit definition version of operationalism which held that since explicit definitions rendered theoretical terms (including intervening variables) eliminable, there was no justification for allowing theoretical terms in science. Hempel (1958) presents the positivistic rejoinder, stressing the importance of systematization and integration which theoretical terms allow.

Criticisms charged that operationalism was trivial or was a minor part of science, needlessly proliferated concepts, ultimately leaves psychological concepts undefined, and makes experimental error meaningless since there is no standard against which operations can be validated. The last charge was rebutted later by development of evaluative notions such as concurrent and construct validity.

4 The operationalist legacy

Although positivism had limited influence in the development of operationalist philosophies, it was an active focus of comparison and dissemination for disparate operationalist views. Scientific practice in psychology and sociology became increasingly behaviourist and operationalist in a manner that minimized fundamental differences. It became commonplace that theoretical terms should be operationally defined, but what that demanded became increasingly unclear.

MacCorquodale and Meehl (1948) crystallized issues when they construed intervening variables as those definable by explicit definitions and hypothetical constructs as those only definable via reduction sentences. Today it is commonplace that operational definitions are required when 'remote' quantitative variables are invoked. Yet exactly what operational definitions come to remains unresolved due to the conflations noted above. Disputes over the adequacy of operational definitions are frequently dismissed as 'mere semantic disputes' - a move appropriate only for stipulative explicit definitions - when they turn on whether the operational definitions correctly capture empirical connections between hypothetical-construct theoretical terms and various observable states of independent and dependent variables.

Nevertheless operational definitions remain an adequacy requirement for social science research.

Optics

Optics as physics concerned with the manipulation and study of light and, more recently, the general study of electromagnetic radiation, has a history back to ancient Egypt, and systematic study to classical Greece. But physics has proved better able to manipulate light than to explain its fundamental nature.

'Geometrical optics' treats light as a bundle of discrete rays, tracing their rectilinear paths reflected from surfaces and refracted through transparent media. 'Physical optics' treats light as a wave. It explains the dispersion of white light into spectral colours, the bands and colour patterns of diffraction phenomena, and aspects of the absorption and scattering of light. Characterizing the way in which the physical aspects of light become the perceptual aspects of shape and colour joins physics, physiology and philosophy in the perennial question of the correspondence of our perceptions to the physical world itself.

A modern view of light describes it in terms of massless particulate photons. This 'quantum optics' treats the absorption and emission of light by matter; providing precise knowledge of matter's inner structure, and the technology of lasers. Philosophically, quantum optics has led to the fundamental question: what is light? What is this natural entity which is created and destroyed in a particle-like way and yet propagates through space - and lenses, holes and slits - in a wave-like way? Experiments in which individual photons interfere with themselves make it hard to think of them as having unique paths. Experiments involving the correlation of photon properties threaten attempts to describe photons as having individual properties and interacting only locally.

1 History

Optical technology goes back at least three millennia. Mirrors made of polished copper and bronze were in use in ancient Egypt. The earliest known theories of light were held by the Greeks, who recognized the rectilinear propagation of light and stated the law of reflection. Lens combinations, in the form of the refracting telescope and microscope, were developed in the sixteenth century, and used notably by Galileo (see Galilei, G. §2). But the historical debate about light relevant to current discussions of its nature began in the late seventeenth century.

Isaac Newton was the chief champion of the corpuscular account of light, holding that the different colours of light he saw in his dispersal of white light by means of a prism were associated with different corpuscles (see Newton, I. §2). His view stood against the undulatory view championed by Christiaan Huygens.

In Huygens' view, light was solely the result of rapidly (but finitely) propagating longitudinal undulations in ethereal matter, undulations which slowed down in denser media (in contrast to Newton's more rapidly moving corpuscles). Huygens was able to derive the laws of reflection and refraction, to explain the double refraction of certain crystals, and to recognize in it a manifestation of a kind of double character to light itself, a 'two-sidedness' as Newton described it, the phenomenon we now call polarization. The wave model was much improved by Thomas Young and Augustin Fresnel in the early nineteenth century. They introduced the revolutionary idea that ethereal undulations could interfere negatively as well as positively, thereby accounting for the diffraction patterns (bands of light and dark) arising from obstacles and apertures.

The peculiar two-sidedness of light remained a problem until Young's suggestion that ethereal undulations were transverse to the ray direction. Polarization was then simply a manifestation of the undulations of the ether in perpendicular directions.

This largely qualitative model of light propagation was rendered firmly quantitative by the work of James Clerk Maxwell in the mid-nineteenth century. Maxwell's concern was with the nature of electrical and magnetic phenomena, and he was able to distill the essence of these phenomena into a very small set of mathematical expressions (see Electrodynamics). From these equations, Maxwell was able to show that an electromagnetic disturbance could propagate as a transverse wave, with a speed determined by basic, and independently measurable, electric and magnetic properties of the medium. When Maxwell substituted known values of these properties into his velocity expression, the number he obtained was the same as that empirically determined (by Fizeau and Foucault) for the speed of light, roughly $186,000$ miles per second. Light appeared to be precisely an electromagnetic disturbance propagated in the form of transverse waves through the ether.

Mathematically, with Maxwell's equations, the modern model of physical optics is complete. But conceptually, a great step had yet to be taken. For though Maxwell's mathematical analysis did not require any physical model of the ether, he remained firmly in the grip of it as a material underpinning. Yet as much as he was unable to imagine an electromagnetic undulation without an underlying undulatory medium, Maxwell nonetheless recognized the electromagnetic field itself as a repository of energy. In a vision with roots in the ideas of Michael Faraday, Maxwell saw the space surrounding electrified and magnetic bodies as suffused with energy. Rather than electromagnetic energy flowing through conductors with the flow of current, it was seen as flowing around and into them from the surrounding immaterial field. This view of the electromagnetic field as an autonomous entity, and light as an undulation in the field itself, is the field theory of physical optics (see Field theory, classical).

2 Classical optics

These two views of light - the remnants of the corpuscular model in ray or geometrical optics and the electromagnetic wave model in physical optics - together define what is called classical optics. Almost all the optical phenomena comprising the world of visual experience, and the many ubiquitous optical apparatus which enhance this world, are generally understood in terms of classical optics.

Geometrical optics traces the rectilinear paths of light reflected from surfaces and refracted through transparent media in an optical system. Such a system, besides mirrors and lenses, may contain prisms, apertures, beamsplitters, gratings, filters, polarizers, diffusers, even fibre bundles. Each ray from an object point is traced through the system to a single point on an image plane. All these points make up the geometrical image of the object as formed by the system.

Where the wave character of light becomes important is in the realm of physical optics. Physical optics treats the entire spectrum of electromagnetic radiation, from radio waves of kilometre wavelengths, through microwaves, infrared, visible and ultraviolet light, to X-rays and finally gamma rays at a thousand-millionth of a millimetre. Though vastly different processes are involved in the emission and absorption of electromagnetic radiation over this range, its propagation through space - and through lenses, holes and slits - is treated in a perfectly unified way by Maxwell's equations and their interpretation; descriptive of an autonomous, energy-containing, yet immaterial field. Polarization, interference, diffraction, are all variations on the basic field-wave property of superposition: the linear combination of the perpendicularly oriented transverse components of multiple waves. Together with aspects of the absorption and scattering of light, they fully account for the shapes and colours we perceive in the world. How our visual universe is created from the processes of physical optics is another matter, however.

3 Vision

Our eyes are highly complex compound lens systems with electrochemical receptors. Place these eyes in the world of physical optics and one does have the means for accounting for virtually all the visual appearance of the world, though it is surprising how many and various are the physico-optical properties of objects that contribute to our perception of them. Still, though the image of the world on our retinas must contain all the information required for seeing, the relationship between that information and the content of our visual field is far from straightforward.

The resolution of detail permitted by our lens-receptor system, understood passively as a camera, is far less than what we actually resolve perceptually. We have blind spots and blood-vessel shadows on our retinas, chromatic aberration and scattering in our lenses, quivering and drifting induced by eyeball musculature, yet we see no vestiges of these in our perceptual world. Clearly, much visual processing goes on in the brain. Unfortunately, the further one moves from the visual receptors themselves and into the activity of the visual cortex of the brain, the less certain our understanding is.

The intimate involvement of the brain in seeing inevitably raises the philosophical issue of the correspondence of the visual field and the real world. Is, for instance, colour a genuine physical property, a combination of physical properties, or supervenient on some set of physical properties? An objectivist would answer the question in the affirmative. A subjectivist might counter that colours are only properties of physical objects in the sense of being dispositions of those objects to affect us visually in the way they do. As our understanding of neurophysiology increases, this debate becomes ever more subtle (see Colour, theories of).

4 Light and relativity theory

Nineteenth-century concerns with the anomalous physical properties of the luminiferous ether, and generations of efforts to detect it, were swept aside conceptually in the early twentieth century by Albert Einstein's special theory of relativity (see Einstein, A. §2). (Michelson and Morley's interferometer experiment in 1887, popularly regarded as definitive, established any velocity of the earth with respect to an ether at less than $4,700$ metres per second. Results from the 1980s limit this to 0.05 metres per second. Manipulation of light continues to have its own dynamic, independent of conceptual revolutions.) In Einstein's theory, the velocity of light is completely independent of the relative velocity of the source or any observer. (This assumption of Einstein's, in turn, has now been tested for relative velocities more than 90 per cent of light speed.) In a spatial analogy, this invariant velocity is like a far object that remains always at the same distance, no matter how one moves.

Conceptually, this anomalous property of light falls right out of the modern formulation of Einstein's theory as a spacetime theory (see Spacetime §2). The intrinsic geometry of nature is four-dimensional, and our experience of it is as three-dimensional space and one-dimensional time, thus our notion of simultaneity and our determinations of velocity, are a function of our relation to this intrinsic geometry, our state of motion. In this formulation, light has a special place, traversing a special set of intrinsic straightest paths in (generally curved) spacetime. It is our locally-variable velocity determinations that produce the universal invariant velocity of light (see Relativity theory, philosophical significance of §§1-2). Its invariance is enshrined in our current choice of world standards: the velocity of light was in 1983 set at its best measured value of 299,792,458 metres per second and the international standard of length was adjusted accordingly. All measured distances must now be thought of as light seconds.

5 Light and quantum mechanics

Einstein is closely associated with the other great twentieth-century revolution in our understanding of light, the quantum or (as it is now called) photon theory (see Einstein, A. §4). In proposing that light is transmitted by free quanta that retain their particulate character as they travel through space, Einstein joined Max Planck in imagining that the exchange of energy between radiation and matter could take place only discontinuously, in energy quanta related to the frequency of the radiation. The myriad interference effects that wave optics explained so readily were to be accounted for by inter-quanta interactions. Niels Bohr's treatment of the spectrum of the hydrogen atom added a crucial third component to this early quantum theory. In Bohr's treatment, atomic electron orbits of only certain energies were allowed. The frequency of radiation emitted and absorbed by the atom reflected the transitions between these discrete electron energy states, with the energy-frequency relation that of Planck.

Bohr's central idea has led to the vast field of modern spectroscopy, in which the emission and absorption of radiation by matter is analysed for astoundingly precise knowledge of molecular, atomic, nuclear and subnuclear structure. (The laser - a coherent, tightly focused beam of light created by the stimulated de-excitation of a population of atoms all excited to precisely the same state - has been one product, and essential tool, of modern spectroscopy.)

But the problem Einstein confronted with his hopes for an inter-quanta interaction theory of light interference now looms larger than ever. For it is now possible to manipulate experimentally single photons of light, and interference effects persist. The classic experiment involves placing a half-silvered mirror, or other beamsplitter, downstream from a light source, creating dual optical paths. (A half-silvered mirror is one in which the metallic coating is too thin to be opaque, so light will be both reflected and transmitted through it.) The presence of single photons is confirmed by correlating detection events in each path: perfect anticorrelation is unambiguous evidence for single photons. Yet when path detectors are replaced by mirrors, and the paths recombined, an interference pattern of individual photon impacts gradually accumulates. This occurs even when (effectively) the choice of mirrors or detectors is made after the light passes through the beamsplitter. It seems difficult to say, prior to the downstream choice of detectors or mirrors, that the light followed a single path (detectors) or both paths (mirrors). Yet surely any sense of unique energetic history would require that circumstance to be decided at the beamsplitter.

Another classic experiment is based on yet another proposal made by Einstein (see Einstein, A. §5) and developed by John Bell in the 1960s (see Bell's theorem). The proposal has to do with multi-component quantum systems, spatially separated after being prepared in such a way that the properties of the individual components are tightly correlated. The results from the separate detections of component properties are predicted to display correlations

that are inconsistent with the two-fold view that the properties established at preparation are retained throughout the individual path histories, and that the measured values reflect only local interactions with the detectors. The experiment involves the preparation from a single light source of pairs of photons with correlated polarizations. Travelling different optical paths, the streams of photons display individual randomly oriented polarizations, which nevertheless upon coincident comparison exhibit the unusual correlations. It seems difficult in this case to maintain the view that the photons can indeed be prepared with determinate properties and then causally separated.

In these experiments the interpretive problems of light merge with the general interpretive problems of the quantum theory (see Quantum mechanics, interpretation of). Our great sophistication in manipulating light places it at the experimental centre of this most profound contemporary controversy.

Ordinal logics

By an ordinal logic is meant any uniform effective means of associating a logic (that is, an effectively generated formal system) with each effective ordinal representation. This notion was first introduced and studied by Alan Turing in 1939 as a means to overcome the incompleteness of sufficiently strong consistent formal systems, established by Kurt Gödel in 1931.

The first ordinal logic to consider, in view of Gödel's results, would be that obtained by iterating into the constructive transfinite the process of adjoining to each system the formal statement expressing its consistency. For that ordinal logic, Turing obtained a completeness result for the class of true statements of the form that all natural numbers have a given effectively decidable property. However, he also showed that any ordinal logic (such as this) which is strictly increasing with increasing ordinal representation cannot have the property of invariance: in general, different representations of the same ordinal will have different sets of theorems attached to them. This makes the choice of representation a crucial one, and without a clear rationale as to how that is to be made, the notion of ordinal logic becomes problematic for its intended use.

Research on ordinal logics lapsed until the late 1950s, when it was taken up again for more systematic development. Besides leading to improvements of Turing's results in various respects (both positive and negative), the newer research turned to restrictions of ordinal logics by an autonomy (or 'boot-strap') condition which limits the choice of ordinal representations admitted, by requiring their recognition as such in advance.

1 Incompleteness, consistency statements and reflection principles

The point of departure for the study of ordinal logics is Kurt Gödel's second incompleteness theorem, also referred to as the theorem on unprovability of consistency (see Gödel's theorems). With each effectively generated formal system *S* containing a modicum of arithmetic is associated the arithmetical statement Con_S of consistency of *S*. If *S* is consistent then Con_S is not provable in *S*, and so the system S' obtained by adjoining Con_S as an axiom to *S* is stronger than *S*. It may, in fact, happen that S' is inconsistent, but if *S* satisfies a condition slightly stronger than consistency (to be described below) so also does S'. Let $\mathcal{C}$ be the class of effectively generated formal systems satisfying this strengthened consistency condition. Thus by beginning with any system S_0 in $\mathcal{C}$ and forming, in succession, $S_1 = S_0', S_2 = S_1', \ldots\}$, we obtain more and more complete systems in $\mathcal{C}$. As will be explained in §2, this procedure can also be extended into the transfinite, since the union of any effectively generated sequence of systems in $\mathcal{C}$ is again in $\mathcal{C}$. In this section, matters concerning formal systems and extension principles such as those of Gödelian type will be explained as needed to make these notions precise. Certain preliminaries from recursion theory and arithmetical definability theory are necessary for this purpose (see Computability theory; Recursion-theoretic hierarchies).

The variables $x, y, z, \ldots$ are here taken to range over the set $N = \{0, 1, 2, \ldots\}$ of natural numbers. For $P(x)$ a property of natural numbers, $\{x \colon P(x)\}$ denotes the set of all *x* in N for which $P(x)$ holds. The class $\sum_1^0$ in the arithmetic hierarchy consists of all sets of the form $\{x \colon \exists y R(x, y)\}$ where *R* is primitive recursive; $\sum_1^0$ is coextensive with the class of recursively enumerable (RE) sets, i.e. those which are effectively generated according to Church's thesis. There is a uniform $\sum_1^0$ enumeration $W_e = \{x \colon yT(e, x, y)\}$ of all $\sum_1^0$ sets for $e = 0, 1, 2, \ldots$, where *T* is a suitable primitive recursive relation; *e* is said to be an *index* of an effectively generated set *W* if $W = W_e$. The only other classes in the arithmetic hierarchy to which reference will be made below are the $\prod_1^0$ sets $\{x \colon \forall R(x, y)\}$ and the $\prod_2^0$ sets $\{x \colon \forall y \exists z R(x, y, z)\}$. (See Recursion-theoretic hierarchies for more information about the $\prod$ and $\sum$ classifications.)

For simplicity, on the formal side we shall deal only with systems whose language is that of first order (or elementary) number theory. Primitive recursive relations may be taken as basic, or defined (by a method due to Gödel) in terms of the operations of addition and multiplication. Either way, we can then speak of formulas in $\sum_1^0$, $\prod_1^0$ and $\prod_2^0$ form (among others). All notions of truth and definability are referred to the standard model, in which the variables are taken to range over *N* and the basic operations and relations receive their intended interpretation.

To carry notions of effectiveness over to the syntactic side, one uses the association with each formula *A* of its

Gödel number, denoted $\#A$. Then the above enumeration of $\sum_1^0$ sets induces an enumeration of sets of formulas, $S[e] = \{A\colon \#A \in W_e\}$; a set *S* of formulas is said to be effectively generated (or RE) if $S = S[e]$ for some *e*, and in that case *e* is called an *index* or *presentation* of *S*. Effective operations on such sets are explained in terms of operations on their indices. Moreover, effective sequences $S_n(n \in N)$ of RE sets of formulas can be considered as given by (an index *f* of) a total recursive function $\{f\}$ with $S_n = S[\{f\}(n)]$ for each *n*. Associated effectively with each such *f* is an index of $\cup_n S_n$ as an RE set.

Gödel's incompleteness theorems apply to effectively generated extensions of a formal system containing a modicum of arithmetic. Most familiar for the latter purpose is the system *PA* of Peano Arithmetic (Peano's axioms in first-order form), though much weaker systems suffice. Thus in the following, only RE sets *S* of formulas will be considered for which *S* includes *PA*. Then *A* is provable from *S* if *A* is a consequence of *S* by means of the axioms and rules of the first-order predicate calculus with identity. For simplicity, we assume that the non-logical axioms of *S* are given as closed formulas, that is, sentences. *S* is *consistent* if it does not prove the sentence $0 \neq 0$, and is 1-*consistent* if each $\sum_1^0$ sentence provable in *S* is true. *S* is called ω-*consistent* if there is *no* formula $A(x)$ for which we have both $\exists x A(x)$ and $\neg A(\overline{n})$ provable in *S* for each *n*. (The notion of ω-consistency was introduced by Gödel in 1931 to show that if *G* is the sentence which expresses of itself that it is not provable in *S* then $\neg G$ is not provable in *S*; it was observed later that 1-consistency suffices for this conclusion.) Finally, *S* is said to be *true* if each sentence of *S* is true. Note that truth implies ω-consistency which implies 1-consistency which, in turn, implies consistency. We write $S_1 S_2$ if every *A* provable in S_1 is provable in S_2, and $S_1 \equiv S_2$ if $S_1 \subseteq S_2$ and $S_2 \subseteq S_1$. S_2 is said to be stronger than S_1 if $S_1 \subseteq S_2$ but some *A* is provable in S_2 which is not provable in S_1.

With each index or presentation e of an effectively generated system *S* is associated a $\sum_1^0$ formula $Prov_S(x)$ which expresses that *x* is the number of a formula provable from *S*. Then the $\prod_1^0$ sentence $Con_S = \neg Prov_S(\#A_0)$, where A_0 is $(0 \neq 0)$, formally expresses the consistency of *S*. (To be more precise, we should write $Prov_e(x)$ and Con_e for these formulas, for each index *e* of *S*.) According to Gödel's second incompleteness theorem, if *S* is consistent (and includes *PA*) then *S* does not prove Con_S. By hypothesis, Con_S is true in this case, but it may be that $S' = S \cup \{Con_S\}$ is inconsistent; however, if *S* is 1-consistent then so also is S'.

For familiar systems *S*, we come to accept their consistency by informally recognizing that each axiom of *S* is true, hence that each sentence *A* provable from *S* is true. The formal statement of the latter recognition can be given in the language of arithmetic without the truth predicate, simply as

(*) $Prov_S(\#A) \rightarrow A$

For, by Tarski's truth criterion (see Tarski's definition of truth), we have $Tr(\#A) \leftrightarrow A$. The collection of all statements of the form (*) is called the *(local) reflection principle* (Rfn_S) for *S*. Note that the instance $Prov_S(\#A_0) \rightarrow A_0$, with A_0 as above, is equivalent to $\neg Prov_S(\#A_0)$, that is, to Con_S. In other words, the consistency of *S* is a consequence of Rfn_S. As with the addition of Con_S to *S*, 1-consistency is preserved under the expansion of *S* by all instances of Rfn_S for which *A* is in $\prod_2^0$ form. However, we must assume a stronger hypothesis for the full extension, namely: if *S* is true so also is $S \cup Rfn_S$. In the following, we shall be concerned with the extensions of systems given by $S' = S \cup \{Con_S\}$ and $S' = S \cup Rfn_S$, among others. In each of these cases, an index of S' is found effectively from one for *S*.

2 Ordinal logics; Turing's results

Passages from *S* to S' for effectively generated *S*, such as described in the preceding section, can be iterated effectively into the transfinite by using closure under effective unions at limit stages. For this one needs a notion of a system of recursive (or 'constructive') ordinal notations. The first such system was introduced in 1936 by Alonzo Church and Stephen C. Kleene using representations of ordinals by certain terms in Church's lambda calculus (see Lambda calculus). Several variants of this system were subsequently introduced which are all equivalent in the sense that the same ordinals are represented by the different systems. One of these was given by Kleene (1938) in more current recursion-theoretic terms as a subset *O* of *N* together with a partial ordering relation $<_O$ between elements of *O* and a map $a \mapsto \mid a \mid$ from *O* into the ordinals, with the property that if $a <_O b$ then $\mid a \mid < \mid b \mid$.

This representation is not in general unique, that is, the same ordinal α may have many $a \in O$ with $\mid a \mid = \alpha$ (if there are any such $a \in O$ at all). The relation $<_O$ is tree-like in the sense that for each $b \in O$, $\{a\colon a <_O b\}$ is linearly ordered by $<_O$.

The system *O* is also equipped with: (i) a unique element 0_O with $\mid 0_O \mid = 0$, (ii) a recursive operation sc_O from *O* to *O* such that for $a' = sc_O(a)$, $\mid a' \mid = \mid a \mid +1$ and (iii) a recursive operation lim_O from indices of recursive increasing sequences of members of *O* to *O*, such that whenever $\{f\}(n) = a_n$ is in *O* and $a_n <_O a_{n+1}$ for all *n* then $\mid lim_O(f) \mid = lim_n \mid a_n \mid$. Finally, *O* is the least set satisfying the recursive closure conditions (i) - (iii). An ordinal α is said to be recursive if $\alpha = \mid a \mid$ for some $a \in O$; in a sense, these are the effectively countable ordinals. The least non-recursive ordinal is denoted ω_1^{CK}, i.e. the least effectively uncountable ordinal (in the sense of Church and Kleene).

Turing's notion of ordinal logic in his seminal 1939 paper was framed in terms of the lambda calculus; moreover, his notion of a logic was idiosyncratic in that he only considered sets of $\prod_2^0$ formulas. Basically, for Turing, an ordinal logic is any effective association of a logic in his sense with each constructive ordinal notation. The following is an adaptation of Turing's notions to the more current recursion-theoretic framework together with the treatment of logics as formal systems in the sense of §1, which respects all of his results.

Thus, by an *ordinal logic* is meant any partial recursive *E* which associates with each $a \in O$ an index $E(a)$ of an effectively generated formal system S_a, so that $S_a = S[E(a)]$. In the rest of this section S_a is assumed to be a set of sentences in the language of arithmetic with $PA \subseteq S_a$. The logic given by *E* is denoted by $\langle S_a^E \rangle_{a \in O}$, and the superscript '*E*' is suppressed when there is no ambiguity. An ordinal logic is said to be *invariant* (*up through* α) if for all *a*, $b \in O$ with $\mid a \mid = \mid b \mid$ and $\mid b \mid \leq \alpha$) we have $S_a \equiv S_b$; it is said to be *increasing* (*strictly increasing, up through* α) if whenever $a <_O b$ then $S_a \subseteq S_b$ (S_b is stronger than S_a, for $\mid b \mid \leq \alpha$). The ordinal logic is said to be *continuous* if whenever *f* represents an increasing sequence in *O*, then $S_{lim_O(f)} = \cup_n S_{\{f\}(n)}$. Finally, it is said to be *complete* for a class *T* of sentences if for each *A* in *T* there exists $a \in O$ with *A* provable in S_a.

Of special interest are ordinal logics obtained in the following way. We suppose given a partial recursive function (called a *succession principle*) which associates with each index of an effectively generated system *S* an index of a system S' extending *S*. Then given any initially specified system S_0 containing *PA*, one can construct an ordinal logic $\langle S_a \rangle_{a \in O}$ such that:

(i) $S_{0_O} = S_0$, (ii) $S_{sc_O(a)} = S'_a$ for each $a \in O$, and (iii) the ordinal logic is continuous. Then given any notion of correctness $\mathcal{C}$ of systems which applies to S_0 and which is closed under the operation $S \mapsto S'$ and under effective unions, each S_a will belong to $\mathcal{C}$. This holds for the collection $\mathcal{C}$ of 1-consistent systems when $S' = S \cup \{Con_S\}$ and for the collection of true systems when $S' = S \cup Rfn_S$. An ordinal logic constructed satisfying (i)-(iii) is said to be based on the succession principle $S \mapsto S'$; it is strictly increasing if S' is always stronger than *S*, for *S* in $\mathcal{C}$.

For the ordinal logic based on the succession principle $S' = S \cup Rfn_S$, Turing obtained completeness for the class *T* of true $\prod_1^0$ sentences. He asked whether one can obtain completeness for the class of true $\prod_2^0$ sentences; this was answered in the negative by Feferman in 1962 (see §3). In any case, Turing's $\prod_1^0$ completeness result is disappointing (as he himself thought) due to the following general result which is obtained: an ordinal logic cannot be strictly increasing and invariant. Thus a true $\prod_1^0$ sentence provable in some S_a need not be provable in an S_b with $\mid b \mid = \mid a \mid$, and so the completeness result is sensitive to which ordinal notations are used.

Closer inspection of Turing's arguments revealed the following. First of all, his completeness result for true $\prod_1^0$ sentences already holds for the ordinal logic based on the succession principle $S' = S \cup \{Con_S\}$. For this, one associates with each primitive recursive predicate $R(x)$ a number a_R such that a_R is in *O* just in case $\forall x R(x)$ is true, and is such that $\mid a_R \mid = \omega + 1$ and S_{a_R} proves $\forall x R(x)$ when that holds. The notation a_R is not 'natural', unlike our usual notation for $\omega + 1$; it is simply fabricated to do this job. Similarly, an ordinal logic can't be strictly increasing and invariant up through $\omega + 1$; this is best possible for continuous ordinal logics, since one has unique notations in *O* for the natural numbers, hence invariance up through ω.

The original aim for ordinal logics was to obtain an association of effective formal systems S_α with ordinals α in

such a way that $S_{\alpha+1} = S'_{\alpha}$ and $S_{\alpha} = \cup_{\beta<\alpha} S_{\beta}$ for limit α. The definition of ordinal logics as assignments $a \mapsto S^E_a$ for $a \in O$ was necessitated in order to make the association effective. Unless one has some canonical way of associating with each recursive ordinal α an $a \in O$ with $\mid a \mid = \alpha$, the notion of ordinal logic is problematic for its original purpose.

3 Subsequent work

Turing did no further work on ordinal logics after 1939, and the subject went into limbo until it was taken up again in the late 1950s by Georg Kreisel and by Feferman. Part of Feferman's work (1962) consisted in recasting Turing's work from the lambda calculus in ordinary recursion-theoretic terms and in sharpening his results, essentially as described in the preceding section. Finally, attention was restricted to continuous ordinal logics based on a given effective succession principle $S \mapsto S'$; these were called *transfinite recursive progressions of axiomatic theories*. The new work in 1962 was for a recursive progression based on the so-called *uniform reflection principle for a logic* S (RFN_S) which consists of all sentences of the form

(**) $\forall x Prov_S(\#A(\overline{x})) \rightarrow \forall x A(x)$

where for each *n*, $\overline{n}$ is the numeral denoting *n*. Thus (RFN_S) for $A(x)$ expresses that if *S* proves $A(\overline{n})$ for each *n* then $\forall x A(x)$ is true, and so it is a kind of formalized ω-rule. The main result of the author's 1962 work was that for the recursive progression based on the uniform reflection principle, we have completeness for *all* true arithmetical sentences. Moreover, one obtains completeness along suitable paths *P* through *O* (i.e. where *P* is a subset of *O* linearly ordered by $<_O$ which contains a representative for each recursive ordinal). Namely, it was shown that there is a path *P* through *O* (and recursive in *O*) such that for each true arithmetical sentence *A*, there exists $a \in P$ with *A* provable in S_a. Now this completeness result is sensitive to the choice of path because of Turing's non-invariance result, and so the crucial question to be raised is: *what is a natural path P through O*? As of the time of writing, there is still no convincing answer to this question. Familiar natural systems of ordinal representation all close off at a recursive ordinal. One feature of these is that they are defined inductively; furthermore, sets generated by arithmetical inductive definitions are in the class $\prod^1_1$ in the analytic hierarchy (as is the set *O*). (See Recursion-theoretic hierarchies for more information about the analytic hierarchy.) It was shown by Feferman and Spector in 1962 that $\prod^1_1$ paths through *O* exist, but that if *P* is any such path then $\cup_{a\in P} S_a$ is incomplete for true $\prod^0_1$ sentences. Hence if the answer to the question about natural paths requires them to be inductively defined, one will have a very strong incompleteness result for recursive progressions restricted to natural ordinal notations.

4 Autonomous progressions of theories and reflective concepts of proof

In order to characterize informal concepts of proof embodying some kind of stepwise reflective character such as that of *finitist proof* or *predicative proof*, Georg Kreisel suggested in 1958 the use of certain ordinal logics restricted by an *autonomy* (or 'boot-strap') condition. The restriction consists in allowing one to advance to an S_a for $a \in O$ only if it has been proved in some previously accepted $S_b(b <_O a$ that *a* is in *O*. Formally, this requires an extension of the language of arithmetic to admit predicates expressing well-foundedness in one way or another. Not so incidentally, imposition of the autonomy condition partially circumvents the problem of which ordinal notations are to be used in an ordinal logic. However, the purposes are substantially different, since autonomous progressions are incomplete for true $\prod^0_1$ sentences and break off at a recursive ordinal.

For the concept of predicative provability in analysis, Kreisel proposed consideration of an autonomous progression of ramified analytic systems. In 1964, Kurt Schütte and Feferman independently obtained a characterization of the least non-predicatively provable ordinal under this proposal. In a 1991 article, Feferman introduced a notion of *reflective closure* of a system *S* which does not require any of the (problematic) machinery of ordinal logics and showed that the reflective closure of *PA* has exactly the same arithmetical consequences as the autonomous progression of ramified systems. It is proposed there that the reflective closure of a system *S* contains everything one ought to accept if one has accepted the basic notions and principles of *S*.

Ordinary language philosophy

Ordinary language philosophy is a method of doing philosophy, rather than a set of doctrines. It is diverse in its methods and attitudes. It belongs to the general category of analytic philosophy, which has as its principal goal the analysis of concepts rather than the construction of a metaphysical system or the articulation of insights about the human condition. The method is to use features of certain words in ordinary or non-philosophical contexts as an aid to doing philosophy. The uses in non-philosophical contexts are taken to be paradigmatic; it is in them that meaning lives and moves and has its being. All ordinary language philosophers agree that classical philosophy suffered from an inadequate methodology that accounts for the lack of progress. But proponents of the method do not agree about whether philosophical problems are solved or dissolved; that is, they do not agree about whether philosophical problems are genuine problems for which there are solutions or whether they are merely pseudo-problems, which can at best be diagnosed.

1 The justification of the method

Ordinary language philosophy flourished between 1940 and 1965. It was practised most vigorously at the University of Oxford although it had distinguished practitioners in places as remote from each other as Nebraska in the USA and Adelaide in Australia. There was no comparable movement in Europe, although the most famous philosopher associated with ordinary language philosophy, Ludwig Wittgenstein, was born and brought up in Austria. Ordinary language philosophy evolved out of logical positivism. Although these two shared a negative opinion of traditional philosophy and promoted the virtues of clarity and precision, their differences are more striking. While logical positivism was scientistic and anti-metaphysical, ordinary language philosophy is anti-scientistic and neutral about metaphysics. It is anti-scientistic because it holds that science is a technical discipline that logically depends upon nontechnical concepts. The argument for this position is that science depends upon technical terms; every technical term must be defined either in words that have ordinary meanings or in other technical terms. If the latter, then these terms themselves must eventually be defined in words that have ordinary meanings since technical terms inherently require an explication in ideas that are already understood. Hence all science depends upon a pre-theoretical understanding of the world. As J.L. Austin said, ordinary language is not the last word, but it is the first ([1961] 1970: 185). Ordinary language philosophy is neutral about metaphysics: some practitioners think that metaphysics can be done and others think that it cannot. There is a similar split over whether such traditional conflicts as realism versus nominalism and free will versus determinism have a resolution.

Behind ordinary language philosophy lies an idea that goes back to Socrates, namely that since language is the expression of thought, studying language is a good way to study the concepts that people have. In order to understand what a cause is, or what truth or knowledge is, it makes sense to look at how people use the words ‘cause’, ‘truth’ and ‘knowledge’. This requires looking closely at situations in which such words can be and are used, and when they cannot be and are not, in order to understand the scope and limits of the concepts they express. Such studies invite the question of the general conditions under which the concepts apply; and that connects the method with traditional philosophical concerns. A presupposition of the method is the anti-Cartesian belief that a person’s mental life is not transparent and that people do not have direct access to their own concepts.

Proponents of the method also believed that most philosophically interesting concepts are more complex and rich than usually depicted and that the surest, if not the only, way to uncover these features is to study the actual deployment of them in a variety of linguistic contexts. One of the great failings of other types of philosophy is therefore supposed to be oversimplification. Austin quipped that oversimplification was not so much the occupational hazard of philosophers as it was their occupation. He thought that philosophers concentrated on one or two favoured uses of a word, when the word itself had a much more complex meaning, which was best revealed by investigating the full spectrum of its uses. Austin resisted the idea that there should be one or two categories into which every kind of object should fit. ‘Why, if there are nineteen of any thing, is it not philosophy?’ he asked. There is another philosophical reason for studying ordinary language. Philosophers care to keep separate things separate. This requires an adequate set of distinctions. Austin believed that ordinary language contained many more distinctions than a philosopher could think up sitting in an armchair, both because ordinary language had to function efficiently for people in a vast array of situations and also because it had evolved over a very long period

of time. For the most part, useful distinctions would survive; useless ones would disappear. Wittgenstein thought that one of the big problems with classical philosophy was that philosophical language did not do any real work: ‘philosophical problems arise when language *goes on holiday*’ (1953: §38; original emphasis).

This helps to explain why Austin wrote a paper about ‘Three Ways of Spilling Ink’ ([1961] 1979). Although the choice of spilling ink was intended to be playful and deflating, a wry allusion to the philosophical enterprise itself, it had a serious purpose. The three ways - deliberately, intentionally and on purpose - are three dimensions that are relevant to the issue of assigning responsibility for an action, clearly a philosophical topic; but previous philosophers had not differentiated between them. Through a series of clever examples, Austin illustrated that there are subtle but important differences between acting deliberately, intentionally and on purpose. There is one further reason why Austin chose to study ways of spilling ink: he wanted a non-momentous, not previously studied action in order to avoid the distortions that come from preconceptions. The distinctions operating within ordinary language are not polluted by philosophical prejudices.

2 Paradigm case arguments

One of the most intriguing and seemingly powerful tactics devised by ordinary language philosophers is the ‘paradigm case argument’. Such arguments were typically deployed to refute scepticism, either in general or with respect to specific items, to show that in (at least some of) speech, some determinate knowledge is presupposed. For example, in order to be able to doubt either that people have hands or that something specific is a hand, the word ‘hand’ must have a meaning; and this meaning is or can be taught by pointing to something and saying that it is a hand. In such a situation, there is no room for doubting that that thing is a hand since it is paradigmatically the kind of situation in which the word is defined. Consequently, the ability to doubt that there are hands presupposes that one knows or did know that something is or was a hand. Thus is scepticism refuted. Variations on this argument were developed to prove that human beings know that they have free will, that the past is real, that some things are red, and that induction and deduction are cogent ways of reasoning. Wittgenstein’s remark, ‘It is part of the grammar of the word "chair" that *this* is what we call "to sit on a chair"’ (1958: 24; original emphasis), has sometimes been taken as at least hinting at the strategy of paradigm case arguments.

However, there are general objections to paradigm case arguments. Even if there are situations in which people say ‘This is a hand (or red)’ in a paradigmatic case of hand-naming (or red-attributing), it does not follow that the intended object of reference is a hand (or red). If the speaker is being deceived by a Cartesian demon or is the subject of a neurosurgeon’s experiment, then what the speaker says may be false, and they may have no way of knowing that it is false. From the fact that a person believes that they are viewing an object under ideal conditions, it does not follow that they are.

Another objection is that the arguments seem to be too strong in the sense that they can be applied to prove that certain things exist that we do not believe exist. For example, one way to explain the meaning of the word ‘witch’, which historically may actually have been used, would have been to point to some woman, probably an old, poor, friendless and unattractive one, and to say ‘That is a witch’. For that community of speakers, that woman would have been a paradigm case of a witch. But very few people today would want to hold that she was in fact a witch. Although proponents of paradigm case arguments wanted to restrict the words that could be taught by paradigm examples, it is dubious that they discovered a principled way of doing this.

3 Criticisms

Ordinary language philosophy tended to offend the unconverted. It often gave the impression of being trite or vacuous; of being concerned merely with verbal issues or semantics. Explicit treatments of how many ways there were to spill ink, or the difference between shooting a donkey accidentally or by mistake did not endear critics, who thought the examples highlighted the triviality of the enterprise and demeaned the profession of philosophy. One philosopher complained, ‘I don’t care how truck drivers talk’, and another that he did not care how Oxford dons talked. This covers the spectrum of one dimension of criticism.

A more general objection is that ordinary language philosophy talks only about words and not things; it seems to glory in verbal disputes and questions of semantics. Austin would have disagreed:

> one thing needs specially emphasizing to counter misunderstandings. When we examine what we should say

> when, what words we should use in what situations, we are looking again not *merely* at words… but also at the realities we use the words to talk about: we are using a sharpened awareness of words to sharpen our perception of, though not as the final arbiter of, the phenomena. For this reason, I think it might be better to use, for this way of doing philosophy,… 'linguistic phenomenology', only that is rather a mouthful.
>
> ([1961] 1970: 182; original emphasis)

Another complaint targeted the Oxonian ideal that philosophers should speak clearly and precisely; it was summarized in the slogan 'Clarity is not enough'. But the ordinary language philosophers never said it was. Clarity was one ideal, preached as a reaction against the German and British idealism of the nineteenth century; not the only one.

The two strongest criticisms were that neither the methodology of ordinary language philosophy nor its results were systematic. These criticisms are independent. One could have a systematic way of studying ordinary language, which would yield the result that ordinary concepts lack the kind of structure that is typically counted as systematized knowledge. And one could hold that systematic results are obtainable using a non-systematic procedure. It is not easy to evaluate these criticisms, and ordinary language philosophers did not agree about the proper response.

4 Systematic methodology and results

Far from being moved by the charges that they did not have a systematic methodology and did not seek systematic results, Wittgenstein and other ordinary language philosophers, including O.K. Bouwsma (1965), would have vaunted them. They thought that one of the chief pitfalls of philosophy was the belief in and desire for systematization, a defect attributable to the desire to make philosophy a science. Wittgenstein always held that philosophy is not like science; it is either higher or lower. Unlike science, which always aims at change in the name of progress, ordinary language and the thinking that it expresses are fine as they are and do not need improvement: 'Philosophy may in no way interfere with the actual use of language, it can in the end only describe it. For it cannot give it any foundation either. It leaves everything as it is' (1953: §124). Behind this idea is the belief, shared by Wittgenstein and G.E. Moore, that ordinary language is the expression of a common sense view of the world that cannot be wrong in its basic components.

Other ordinary language philosophers would deny that they apply no systematic method. Austin adumbrated a methodology explicitly in several essays, notably 'A Plea for Excuses' ([1961] 1970), and the method was refined by Avrum Stroll (1973). In any case, it may be unfair to require a strict methodology of ordinary language philosophy since the idea that scientists proceed according to a strict methodology is dubious.

Even if there were no systematic methodology, that would not preclude an orderly investigation of a phenomenon; one dictated by the phenomenon itself. P.F. Strawson treated the foundations of logic in an orderly way, in the course of arguing that the project of formal logic to codify inferences in general must fail because 'ordinary language has no exact logic'. Although Strawson does not employ a systematic methodology in a technical sense, he is not averse to systematic results. In *Individuals* (1959), he presents what he takes to be the general conceptual scheme by which humans conceive all of reality.

Neither proceeding with a fixed methodology nor proceeding systematically determines whether one's results will be systematic. Stroll used a systematic methodology to study the concept of surfaces (1988); and one of his central results is that there is no one concept of surface, but many, which sometimes intermingle. This result is part of a broader claim that humans categorize the world in a piecemeal fashion. Thus Stroll would deny the fairness of the claim that ordinary language philosophy has no methodology and would hold that the application of his method reveals that there is no single, neat system that humans use to think about surfaces. And yet Stroll does not eschew generalization. He formulates theorems, as general as the subject allows, about various concepts of surfaces, each of which has limited applications.

The most lasting results of ordinary language philosophy have been in the philosophy of language. While there is a difference between ordinary language philosophy, which tries to solve philosophical problems by studying bits of linguistic usage, and the philosophy of language, which tries to give a general account of what language is and how it functions, interest in one is often accompanied by interest in the other. Austin and Grice devised powerful

theories of speech acts and conversation, respectively, complete with technical vocabularies (see Speech acts). John Searle and Zeno Vendler, who were trained by these philosophers and practised ordinary language philosophy early in their careers, have also produced lasting work in the philosophy of language.

At the opposite end from searching for systematic results is the practice of deconstruction. Although it is usually associated with continental philosophy, a good case can be made for applying the term to some ordinary language philosophy. Deconstruction is the tactic of showing that some philosophical distinction is hopelessly flawed, usually because the characterizations of the terms are incoherent. In *Sense and Sensibilia* (1962), Austin showed that the distinction material/immaterial was bogus and led to mistakes. In *Surfaces*, Stroll showed how the apparently proper distinction direct/indirect does not have general application. In particular, this distinction almost never makes sense in application to perception, and its misapplication has led to serious mistakes in the theory of perception.

A renewed interest in metaphysics, partially attributable to Strawson's book *Individuals*, the development of powerful logical theories that could be used to describe natural languages, and a renewed interest in scientific treatments of the mind contributed to the decline of ordinary language philosophy in the late 1960s. The techniques and insights of ordinary language philosophy were no longer conspicuous in philosophy during the 1990s, but some of them had been incorporated into it.

Ordinary language philosophy, school of

The label 'ordinary language philosophy' was more often used by the enemies than by the alleged practitioners of what it was intended to designate. It was supposed to identify a certain kind of philosophy that flourished, mainly in Britain and therein mainly in Oxford, for twenty years or so, roughly after 1945. Its enemies found it convenient to group the objects of their hostility under a single name, while the practitioners thus aimed at were more conscious of divergences among themselves, and of the actual paucity of shared philosophical doctrine; they might have admitted to being a 'group' perhaps, but scarcely a 'school'. The sharp hostility which this group aroused was of two quite different sorts. On the one hand, among certain (usually older) philosophers and more commonly among the serious-minded public, it was labelled as philistine, subversive, parochial and even deliberately trivial; on the other hand, some philosophers (for instance, Russell, Popper and Ayer), while ready enough to concede the importance in philosophy of language, saw a concern with ordinary language in particular as a silly aberration, or even as a perversion and betrayal of modern work in the subject.

How, then, did 'ordinary language' come in? It was partly a matter of style. Those taken to belong to the school were consciously hostile to the lofty, loose rhetoric of old-fashioned idealism; also to the 'deep' paradoxes and mystery-mongering of their continental contemporaries; but also to any kind of academic jargon and neologism, to technical terms and aspirations to 'scientific' professionalism. They preferred to use, not necessarily without wit or elegance, ordinary language. (Here G.E. Moore was an important predecessor.) Besides style, however, there were also relevant doctrines, though less generally shared. Wittgenstein, perhaps the most revered philosopher of the period, went so far as to suggest that philosophical problems in general actually consisted in, or arose from, distortions and misunderstandings of ordinary language, a 'clear view' of which would accomplish their dissolution; many agreed that there was some truth in this, though probably not the whole truth. Then it was widely held that ordinary language was inevitably fundamental to all our intellectual endeavours- it must be what one starts from, supplying the familiar background and terms in which technical sophistications have to be introduced and understood; it was therefore not to be neglected or carelessly handled. Again it was urged, notably by J.L. Austin, that our inherited everyday language is, at least in many areas, a long-evolved, complex and subtle instrument, careful scrutiny of which could be expected to be at least a helpful beginning in the pursuit of philosophical clarity. It was probably this modest claim- overstated and even caricatured by its detractors- which was most frequently supposed to be the credo of ordinary language philosophers. It was important that Russell - like, indeed, Wittgenstein when composing his Tractatus Logico-Philosophicus (1922) - firmly believed, on the contrary, that ordinary language was the mere primitive, confused and confusing surface beneath which theorists were to seek the proper forms of both language and logic.

1 The 'ordinary language' label

It is not at all easy to discern the historical origin of the label 'ordinary language'. Other philosophical schools do not present this difficulty; pragmatists, for instance, or logical positivists consciously, even proudly, identified themselves as such. But being an ordinary language philosopher seems always to have been something of which one was accused, rather than something which one claimed. The philosophers so designated were a roughly recognizable group, but they would certainly have objected to the suggestion that they formed a 'school'. That suggestion seems to have originated among those seeking to set up a convenient target to attack; those attacked would mostly not have claimed the label for themselves, and indeed would probably have objected, not disingenuously, that it was unclear to them what it was supposed to mean. We must first ask what this group (rather than school) comprised, and why it was regarded in some quarters with such remarkable hostility.

After anticipatory stirrings in the pre-war years, the philosophical 'tendency' in question flourished from 1945 for roughly the next twenty years, being confined almost wholly to the sphere of philosophy in English, and within that sphere chiefly, if only through weight of numbers, to philosophy in Oxford. 'Oxford philosophy' was, in fact, an alternative label which had some currency at the time. Here the position of Wittgenstein is a perturbing factor. Among 'Oxford philosophers' he was, well before the publication of *Philosophical Investigations* in 1953, the most esteemed and influential of contemporaries; on the other hand he lived and worked, somewhat reclusively, in Cambridge rather than Oxford, and also (less trivially) himself regarded Oxford as 'a philosophical desert', the meagre fruits of which were to him utterly distasteful. The explanation of this odd state of affairs is partly that

Wittgenstein was temperamentally incapable of attachment to any group of which he was not the acknowledged leader; and partly that, while ‘Oxford philosophy’ was certainly closely akin in substance to Wittgenstein’s later work, its characteristic cool, ironic urbanity of manner was odious to him, wholly lacking in the *Sturm und Drang* which really serious philosophizing entailed. Thus it came about that, while Wittgenstein was always conspicuous among those arraigned as ‘ordinary language philosophers’, he himself would furiously have disclaimed any kinship with the other targets of that critical fire.

Why did ordinary language philosophy incur such hostility? There were two quite distinct reasons. The first, put succinctly, was that in certain quarters it was confusedly regarded as a species of, or a descendant of, logical positivism (see Logical positivism). Old-fashioned philosophers, and many high-minded members of the general reading public, had of course been outraged - as it was intended that they should be - by the brisk dismissiveness of, for example, A.J. Ayer’s *Language, Truth and Logic* of 1936; and it was easily though wrongly supposed for many years thereafter that ‘young’ or ‘modern’ English-language philosophers were all more or less of the same deplorable party - iconoclastic, sceptical, irreverent, subversive of true seriousness - all logical positivists. More significant, however, was the hostility of some leading figures from well within the professional circles of philosophy itself: Russell perhaps most conspicuously, but also, for example, Popper and, perhaps less vehemently, Ayer. This will be explored further in §3 below; but the basic charge here was that ‘Oxford’ or ‘ordinary language’ philosophy was an aberrant, trivializing perversion of good philosophical practice, substituting, in place of honest theorizing and argument, pedantic scrutiny of intrinsically uninteresting detail. The target-figure here seems to have been a most unlikely-looking amalgam of Wittgenstein and J.L. Austin - the former cast as the heresiarch, perhaps, the latter as the pedant. The most furious onslaught was made, with Russell’s blessing, in Ernest Gellner’s *Words and Things* (1959).

2 General character of the ‘school’

To a more than trivial extent, membership of the group in question was a matter of style. There was a conscious hostility to the lofty, rather loose rhetorical manner of, for example, its idealist predecessors; this did not preclude - as the writings of, say, Gilbert Ryle sufficiently illustrate - elegance and wit, but it ruled out eloquence and uplift. (Here, once more, Wittgenstein is a perturbing factor. Though his presence broods, so to speak, over the group, the style of his own writings is absolutely idiosyncratic, personal to himself, seemingly owing nothing to any predecessor, and unlike that of any contemporaries, even of his own disciples.) There was an even more emphatic distaste for the riddle-spinning, paradox-delighting ‘deep’ discourse of most contemporary continental philosophers, with whom, indeed, any kind of academic communication was neither sought nor, probably, practicable. (In this particular distaste there was, I think, an element of moral disapproval; it was felt that the weird, mind-boggling pronouncements of some continental sages were not only unprofitable but largely bogus - an intellectual fraud.) So far, the doggedly plain-man manner of G.E. Moore was a significant influence; nor, so far, does the ‘ordinary language’ style much diverge from that of logical positivism (see Moore, G.E. §3). There is, however, a further point to be made. It was characteristic of logical positivism that, while certainly hostile to philosophical uplift and eloquence, it regarded mathematics and the physical sciences with special reverence; and this tended in philosophical writings towards a liking for the highly regimented handling of batteries of specially introduced technical terminology. This too the ‘ordinary language’ school typically avoided. This was not a matter of dogma: Austin, for example, was entirely happy to employ invented technical terms in his work in the philosophy of language when he felt a clear need for them; it was rather that members of the group did not particularly like philosophical technicality or neologism, suspecting that it was usually unnecessary and often did more harm than good. A large part of the reason for applying the ‘ordinary language’ label was that it was in entirely - and deliberately - ordinary language that those so identified almost always wrote and debated.

A point of more philosophical substance was that members of the ‘ordinary language’ group were unfriendly, at the very least, towards the idea of philosophical ‘theories’. In practice this took the form of a deliberate abstention from the pursuit of generality, of wide-ranging explanations or justifications, of purportedly systematic examination of whole families of concepts; as Bernard Williams has observed, in the relevant period ‘"Piecemeal" was a term of praise.’ Limited issues were to be addressed strictly one at a time, particular concepts brought, as it were, individually under the microscope, and each thoroughly dealt with before going on to another. It was often remarked that the typical ‘Oxford’ philosopher of the post-war years recorded his researches in discrete papers and articles rather than in whole books; and it is worth noting that as early as 1933 the periodical *Analysis* was

launched with the specific aim of promoting and publishing papers far shorter, far more tightly circumscribed in intention than the usual offerings to established philosophical journals.

Diverse motives were at work here. In the case of Wittgenstein himself and his closest followers, theory was rejected as being fundamentally out of place in, inappropriate to, philosophy; it was held that the problems of philosophy were essentially not the sort of perplexities for which theory-construction could offer any solution - even, perhaps, that to talk of 'solution' was itself to put the case in false terms. This must be further considered in what follows. For Austin, however, and probably for many others, the preference for 'piecemeal' working was a simpler matter of prudently limited ambition, of not biting off more than one could analytically chew. It was felt - in this following Moore - that much traditional philosophy had come to grief through the attempt to settle far too much far too quickly; impatient to get to the great work of theory-construction, philosophers had too often simply neglected or hastily over-simplified or carelessly misrepresented the relevant detail, with the inevitable consequence that the theories turned out to be chimerical and often laughably fragile. It was not that theory was held to be intrinsically out of place; it was simply that, in the current state of philosophical affairs, it was premature and over-ambitious. What was felt to be needed at the time was patient spadework - walking, even plodding if necessary, before trying to run. It was probably in this respect that the ordinary language group was most clearly not to be identified with logical positivism; for the latter, after all, was itself a highly ambitious theory, and fundamentally a theory of meaning, which was indeed supposed capable of settling, rigorously and in fairly short order, almost everything. The first chapter of *Language, Truth and Logic* is entitled 'The Elimination of Metaphysics'; the last is entitled 'Solutions of Outstanding Philosophical Disputes'. It was Austin in particular who regarded such sweeping claims as not only injudicious and unjustified, but as rather disreputable.

3 Philosophical tenets

In dealing more directly with the distinctive philosophical tenets of the ordinary language group, one must begin with the later views of Wittgenstein - not, as has been noted in §1 above, because he would have claimed or conceivably tolerated classification as a member of that group, but because first, he was a pervasive, even dominant influence on those who were its members, and second, in his later work 'ordinary' language was accorded a particularly clear and fundamental place.

The story, briefly, is this. In the early work that issued in the *Tractatus Logico-Philosophicus* of 1922, Wittgenstein had sought - then following quite closely lines laid down by Russell - to work out and exhibit the essence of all language, its really fundamental character and mode of working; and this he found in the fundamental relation, on which all meaning depended, between what he called elementary propositions and atomic facts, a relation which he called 'picturing'. But of course the propositions that occur in the actual use of language are, he held, never themselves elementary propositions. So what are they? The answer seemed to lie ready to hand: they are - they could only be - truth-functional compounds of elementary propositions, constructions, in accordance with the principles of Russellian logic, from the necessary though nearly undetectable basic material. It was, of course, to be not only admitted but emphatically affirmed, that languages in their ordinary use do not look at all like this; no one, if asked simply to observe a language and describe it, would arrive at anything resembling this description. But the reason for this was held to be that the surface of language, its easily-visible features, were radically confusing and misleading as to its essential character; the theorist must seek to find, beneath or behind mere surface vagueness and superfluities, the essential structure that - according to theory - must be there (see Russell, B. §9; Wittgenstein, L.J.J. §§3-5).

Briefly, over the next ten years or so, Wittgenstein came to two conclusions: first, that the theory of the *Tractatus* was not in fact the rigorous unveiling of fundamental truth from behind misleading surface phenomena, but was rather the perverse foisting upon the real world of artificial and fantastic theoretical preconceptions; and second, crucially, that this was the general character of philosophical theorizing, and the genesis of all philosophical problems and perplexities. 'Philosophical theories are a product of the imagination, and they offer us simple, but seemingly profound pictures, which blind us to the actual complexities of language. The new philosophy is an organized resistance to this enchantment, and its method is always to bring us back to the linguistic phenomena, with which we are perfectly familiar, but which we cannot keep in focus when we philosophize in the old way' (Pears 1971: 16). Or in Wittgenstein's own words: 'What *we* do is to bring words back from their metaphysical to their everyday usage'; and again: 'We must do away with all *explanation,* and description alone must take its

place' (1953: §116, 109). This is 'ordinary language' philosophy in the fairly strong and precise sense that it holds that a clear view, a plain description, an uncorrupted grasp of ordinary language will exorcize, so to speak, philosophical perplexity, which arises when familiar concepts are, at the supposed behest of 'theory', crudely mishandled: 'the idea is that in philosophy to theorize is to falsify, and the facts about language are offered as a corrective' (Pears 1971: 38). This thesis is very close to that of Wittgenstein's near-contemporary, Gilbert Ryle, as set out in his 'Systematically Misleading Expressions' of 1932 and developed in his later description of philosophy as, essentially, the rectification of 'category mistakes' (see Ryle, G. §1). Almost all members of the ordinary language group accepted the thesis, more or less fervently, as an illuminating contribution to the handling of some of the problems of philosophy, though few would have ventured to maintain, as Wittgenstein at least appeared to do, that every philosophical problem had this linguistic origin and was amenable to this linguistic treatment. Austin in particular was always explicitly opposed to any suggestion that 'philosophical' problems were of any single sort, or that any simple strategy or method would be appropriate to every case.

A different point may be made by reference again to Ryle. In discussing what he calls the 'very misleading phrase "ordinary language",' he says, 'I do think that a philosopher's arguments, when couched in technical terms, tend either to elude one or in fact to go agley. It's much easier to catch a philosopher out, including oneself, if he is not talking in technical terms with which you are unfamiliar, and the most important thing about a philosopher's arguments is that it should be as easy as possible for other people, and especially for himself, to catch him out if he can be caught out' (Magee 1971: 111). This fairly modest idea, which surely owes a good deal to the practice, if not to any stated doctrine, of G.E. Moore, was very widely accepted. It would not have been held that there was no place in philosophy, ever, for invented technical terminology, but it certainly was held that such terminology should always be regarded warily, even with suspicion. Even, for instance, the fairly harmless-looking term of art 'sense-datum' was held to be a potentially damaging stumbling-block in the philosophy of perception (see Austin's *Sense and Sensibilia* (1962)).

A rather different, but again not particularly controversial tenet was that 'acquiring the use of technical vocabularies can only take place against a background of ordinary language…ordinary language is the basis on which technical language is erected to begin with' (Caton 1963: ix). Roughly, technical terms are defined, some no doubt in other technical terms, but ultimately in non-technical, everyday terms. Unless we are clear and careful in our handling of those terms, hoped-for technical refinements will be liable to lapse into confusion.

One should bring in here a related but, for a time, far more ambitious thesis, which became known in the literature as 'the paradigm case argument'. This was the claim that in the general interests of lucidity one should not only accurately describe the ordinary use of expressions; one can also appeal to the fact that an expression has an ordinary use as a cogent argument in itself. If an expression is in established, ordinary use, then its meaning will be settled (and learned) by reference to the standard or paradigm cases in which it is applied by speakers of the language; and if it really is in ordinary use, there must be such cases. But this general truism may seem to have highly important implications. The verb 'know', for example, is in common use; we can all recognize 'paradigmatic' cases in which a person would be said to know something. If so, that is what knowledge is, and in those cases there is knowledge. One need say no more in refutation of scepticism. Or consider the case of denial of freedom of the will. It will not - cannot - be denied that there are paradigmatic, 'meaning-illustrating' circumstances in which people are ordinarily said to do things freely, of their own free will. If so, that is what free will is, and there *is* free will. To deny that there is free will, while conceding, as of course one must, that certain instances actually occur which are standard examples of what 'acting freely' ordinarily means, is not merely to take up a position which no sensible person would accept: it is to propound a thesis which could not be true, which seems indeed self-contradictory.

One can see why this form of argument was, for a time, highly appealing. It was, in the preferred style of the period, satisfactorily deflationary. It was both simple and, at least, plausible. It seemed that ordinary language, at this point at least, could do real philosophical work. Nevertheless, though the paradigm case argument was accorded much powder and shot by such vehement critics as Ernest Gellner (1959: 30-7), it probably never had many wholehearted supporters. It was not only that it seemed altogether too quick, even slick, uncomfortably suggestive of some philosophical sleight-of-hand. It had more serious deficiencies. In many cases it seems not really to engage with the problem at issue. In the case of free will, for example, even if it were taken as establishing that there are - must be - 'paradigmatic' instances of persons acting freely, perhaps not much is

achieved, for the perplexed philosopher is probably not inclined to deny that that is so; his worry is that he cannot see how it could be so, given other things that we wish to preserve, such as scientific principles; and on that the quick argument sheds no light at all. But no doubt the most serious deficiency was always that the quick inference from ‘ordinary use’ to the existence of actual instances was highly insecure. That the use of an expression is current and well-established in the language does not show that such use is, in all or even any respects, justified and legitimate. There was at one time, and no doubt still is, a meaning and ordinary use for the words ‘witch’ and ‘leprechaun’, but we are not obliged to conclude that there are or were witches or leprechauns. The reality of miracles is not deducible from the currency in English of the word ‘miracle’.

Less ambitious and less controversial was the view, associated particularly with J.L. Austin, that ordinary language can sometimes be a valuable philosophical resource (see Austin, J.L. §2). At least in areas of general, perennial human concern - in perception, for example, or human action and behaviour - natural languages will be found to have evolved highly complex and often subtle (though familiar) vocabularies and idioms, so devised as to mark genuine distinctions that have been found to be of importance. If so, then it will surely be prudent for philosophical discussion in such areas at least to begin with careful and comprehensive scrutiny of the relevant ‘ordinary’ vocabulary, the distinctions and connections found there being probably ‘more sound…and more subtle, at least in all ordinary and reasonably practical matters, than any that you or I are likely to think up in our armchairs of an afternoon - the most favoured alternative method’ (Austin 1960: 182).

It was probably this view of Austin’s which was most commonly taken to be the central characteristic credo of the ordinary language group, and not wholly unfairly - it was a view very widely accepted both in theory and practice. Critics, however, too often fanned the flames of their hostility by grossly overstating the claim that was being put forward. It was suggested that Austin was peddling a comprehensive panacea for all philosophical ills - suggesting that exhaustive examination of ordinary language would be, for the resolution of every philosophical problem, the only fruitful and necessary procedure. But this was a crude caricature. Austin was always insistent that the problems assembled under the name ‘philosophy’ were of very many quite different sorts, needing quite different treatments. What he said, and many agreed with him, was that, in suitable cases, scrutiny of the resources of ordinary language would probably be one good way to begin.

Finally, however, it may be that what most firmly united the members of this ‘school’ or group was the simple belief that ordinary everyday language was interesting, deserving of attention, worth investigating. A famous illustration of this would be the contrast between Russell’s article ‘On Denoting’ of 1905 and Strawson’s ‘On Referring’ of 1950. Both address the same issue - certain problems raised by the use of so-called definite descriptions, such as ‘the author of *Ulysses*’. But whereas Russell glances rather perfunctorily at what he took here to be the muddled primitive practices of ordinary language and hurries on to the construction of his own Theory of Descriptions, Strawson finds our own everyday practices of referring to things both interesting and important, and indeed such that, if accurately described, they reveal as unnecessary the revisionary formalization which Russell attempted. There is a somewhat similar contrast between Ayer’s *The Foundations of Empirical Knowledge* (1940) and Austin’s *Sense and Sensibilia*. Ayer’s real interest is in epistemology and the theory called phenomenalism; ‘what we say’ in the field of perception seems to him fairly trivial (see Ayer, A.J. §3). Austin, by contrast, finds our everyday language on perceptual matters to be quite rich, complex and subtle, and again (he perhaps hints) such that, if we accurately describe it, we may in the end see no need for the invention of new terminology or the continuation of theories. I would mention here also A.R. White’s *Modal Thinking* (1975), a book which deliberately eschews the technicalities and problems of formal modal logic in favour of detailed examination of the use and interconnections of such everyday expressions as ‘possible’, ‘can’ and ‘may’.

4 Later developments

It was perhaps inevitable that the philosophical ‘frame of mind’ described here should in time not so much wither away as evolve into something different. Essentially, what proved unstable in the ordinary language outlook was the rejection of theory, the deliberate abstention from generalization in favour of the ‘piecemeal’, case-by-case scrutiny of discrete particulars. The desire to generalize, to unify, to understand, to find patterns and connections and system seems too profoundly characteristic of philosophy to be long suppressed. Furthermore, the question came increasingly to be raised: why should it be suppressed? It had been held, notably by Austin and in practice by many others, that generalization and theory-construction was dangerously over-ambitious and premature; but

surely it could not be premature for ever; and ambition need not be wholly renounced. Wittgenstein, indeed, had gone further. He had rejected all theory, all 'explanation', as not merely premature but as radically misconceived and inappropriate to philosophy, but that depended on his own view of what philosophical problems are and what philosophy is - a view which, as remarked above, was never very widely accepted as the whole truth. Thus philosophers came increasingly to ask (perhaps some had never really ceased to ask): is small-scale piecemeal description really enough? Why should one not try to explain, to interconnect, to paint a general picture? Why, in short, should one not have a theory? Such a progression seems particularly clear in the work of P.F. Strawson (see Strawson, P.F. §§2-8). We have, in 'On Referring', the careful delineation of part of the use of everyday language, its use in referring to individual items. But this led on, in *Individuals* (1959), to the theory that a certain class of items - substantial spatiotemporal individuals - provides the basic targets of reference and subjects of predication. And in due course the further questions of why that should be so and whether it might have been otherwise led into the quite self-consciously quasi-Kantian theorizing of *The Bounds of Sense* (1966). But that is merely one good example of what occurred very generally - namely, from about 1960 onwards, a massive resurgence of the readiness to theorize, to seek not merely to observe but to understand, not merely to describe but to explain. The work of the 'ordinary language school' will perhaps have been justified if the products of this resurgence are found to be less crude, less obscure, less hastily fabricated, and less fragile than have been all too many philosophical theories of the past.

Oresme, Nicole (*c.*1325-82)

Nicole Oresme, a French thinker active in the third quarter of the fourteenth century, occupies an important position in late medieval natural philosophy. He was especially notable for his mathematical approach, in which he represented the intensities of qualities and of speeds by geometrical straight lines, which allowed them to be 'plotted' in principle against both distance and time. He held that the shapes of the resulting graphs would then have explanatory force in the manner of ancient atomism, but, like the latter, his doctrine had a weak empirical basis. His graphical representations of speed have been compared to those later given by Galileo, but there are no grounds for positing influence. He was prominent in developing a particular mathematical language of ratios, which had earlier been used by Thomas Bradwardine to propose a 'law' relating speeds to forces and resistances, and Oresme likewise applied the language to cosmological and physical questions. He was a firm opponent of much of astrology and of magic, and to this end he employed both naturalistic and sceptical arguments. He gave many strong arguments in favour of a daily rotation of the earth, but finally concluded that it was at rest: his gambit had primarily a sceptical and fideistic purpose.

1 Life

Originating from Normandy, Oresme was educated at the University of Paris, where in 1348 he entered the College of Navarre (a royal foundation), and in 1356 became master of its theological class and hence Grand Master of the whole college. Soon afterwards he came into close contact with the royal court, and was in a more or less formal sense a tutor to the Dauphin, who in 1364 ascended the throne as Charles V. Oresme's association with the court remained through a variety of ecclesiastical appointments, culminating in that of the bishopric of Lisieux in 1377.

Oresme's writings are grounded in traditional Aristotelian scholasticism, but informed by an acute mathematical consciousness and coloured to an extent by incipient humanistic currents. The result is an elegant and urbane scepticism, which is nevertheless powered by a strong desire for scientific knowledge and, although Oresme's works cover a wide range of philosophical topics, his main importance lies in issues affecting cosmology and natural philosophy.

2 Mathematics and mathematical physics

Oresme was capable of seeing the world in strongly geometrical terms, to such an extent that he has often been compared with Descartes and his famous claim that his physics was nothing but geometry. Oresme, however, was not so strongly reductionist, and his geometrical picture is richer and more complicated. A central idea was that qualities could be represented at any point by straight lines erected perpendicularly to the subject that they informed (in the case of a linear or two-dimensional subject), proportional in length to the intensity of the quality. In the case of a solid subject, this would ideally have given rise to a four-dimensional configuration for each of its qualities, but because the space available to him was dimensionally limited Oresme conceived it as being conflated by superposition into three dimensions. Oresme then maintained that the shape of the configuration would have explanatory power, so that, for example, a quality that displayed a saw-like 'graph' would be especially pungent. Oresme was very excited by the potential explanatory capabilities of his 'imagination', and explicitly compared his doctrine to ancient atomism (see Atomism, ancient). Nevertheless, it must be admitted that the empirical basis was weak: Oresme did not specify how the differing intensities of qualities should physically be measured, and rather mutedly admitted that 'the ratio of intensities is not so properly nor so easily attained by the senses as the ratio of extensions' (*De configurationibus*).

By Oresme's time there was a growing tendency, especially through the influence of the so-called Oxford Calculators, to treat speeds by analogy with qualities (see Oxford Calculators). Within the Aristotelian tradition, motions and their speeds were essentially holistic, with the focus being on the whole motion of the whole body from its beginning to its end. Using Oresme's mathematizing approach, this gave rise to a view of the speed of a body's motion as a sort of five-dimensional object, with three spatial dimensions (those of the subject), one temporal dimension and one dimension of intensity of speed. If we focus on the motion of a point, this reduces the dimensions to two, with intensity of speed being plotted against time. This allows for comparison of different speeds: for instance, a speed whose intensity increases uniformly through time can, by equation of areas, be shown

to be equivalent to a uniform speed with the intensity that the non-uniform speed had at half-time. This is close to an essential theorem of Galileo in his *Two New Sciences*, and even the diagrams are reminiscent of each other (see Galilei, Galileo). This has given rise to much discussion of the possible influences of fourteenth-century discussions on later mechanics. The issue is still open, but probably actual influence did not extend much beyond the idea (obvious to us, but not always so) of representing instantaneous velocities or intensities of speeds by straight lines proportional in length to their magnitudes.

Problems of measure did not end with the representation of physical quantities by straight lines: these themselves had to be measured, and in the Middle Ages in this context the language of ratios (not usually regarded as being themselves numbers or fractions) was especially important. This rested on the intuition that a meaningful numerical expression of the quantity of a straight line could only be given (assuming that one did not regard the line as being made up of a certain number of points) by comparison with another line. Sometimes this was achieved tacitly by the assumption of one straight line to act as unit, but in most theoretical discussions two or more lines were explicitly brought into play, so that we could give an expression of the mutual measure of *A* to *B* by saying, for instance, that they were as 19 to 13. This was unproblematic for rational ratios, but not when it was a question of expressing the ratio of two incommensurable quantities. In Book V of the *Elements*, Euclid had given a sophisticated criterion (usually ascribed to Eudoxus) for equality between ratios in general (see Mechanics, Aristotelian), but this was often misunderstood and little used in the Middle Ages, and in any case did not give a quantitative expression of the size of the measure.

A more interesting development came from the musical tradition, and depended on a peculiarity of mathematical language. This tradition depended heavily on ratios, and allowed for their combination so that, for instance, combining the ratios of 7:5 and 5:4 gave rise to the ratio of 7:4. This was often regarded as addition, whereas we should be more inclined to think in terms of the multiplication of the corresponding fractions. Nevertheless the addition view gave rise to a perfectly coherent theory, which easily led by extension to the multiplication and division of ratios by numbers, and in turn to the possibility of numerical expressions of the sizes of at least some irrational ratios. There are some hints of this in Robert Grosseteste, but in the early fourteenth century Thomas Bradwardine developed the theory more explicitly, showing for instance how the ratio of the diagonal of a square to its side, which we should say was as $\sqrt{2} : 1$, could be numerically expressed or ‘denominated’ as ‘half of the double ratio’. Bradwardine did not provide much systematic development of the pure mathematical theory of denominating ratios, but this task was undertaken by Oresme in his *Algorismus proportionum (Algorism of Ratios)* and *De proportionibus proportionum (On Ratios of Ratios)*. He clearly showed how ratios partook of the nature of continuous quantity and could be multiplied by any fraction, but also that there were still probably irrational ratios that were not commensurable with any rational ratio, and hence were not susceptible of denomination by the new techniques.

Bradwardine made use of his language of ratios to give expression to a new law of motion, which has sometimes been regarded as radically anti-Aristotelian. In fact, given the addition view of the composition of ratios, it could (at the time) be regarded as a perfectly natural interpretation of Aristotle and his commentator, Averroes (see Ibn Rushd). The law was adopted by Oresme, who expressed it as: ‘Speed follows the ratio of the power of the mover to the thing moved, or its resistance’ (*De proportionibus proportionum*). It is thus syntactically very simple but, if translated into modern mathematical language, it demands the use of a logarithmic or exponential function, which does violence to the context of its origin. Oresme, who with his very systematic approach to ratios could focus clearly on ratios between ratios, was concerned to show that, given any two unknown ratios (rational or irrational), it was probable that they were incommensurable with each other and, if so, then given any two speeds, it was probable that they were incommensurable with each other. This result was a major feature in his attacks on many aspects of contemporary astrology.

3 Astrology and magic; naturalism and scepticism

Oresme was a prominent opponent of both astrology and magic, and some of his criticisms were clearly intended for the ears of members of the French royal court. To this end one of his anti-astrological tracts was written in French, and although like all contemporary Western scholars, Oresme’s customary literary language was Latin, he was also a pioneer in writing philosophical treatises (including some Aristotelian translations) in the vernacular. With the possible exception of his *Questio contra divinatores horoscopios (Question Against Horoscopic*

Divinators), Oresme did not deny the reality of astrological influences, but he did contest the ability of men to make predictions from them except in the most general of ways, and he warned against the moral dangers of attempting to do so. One of his most sophisticated, although possibly least effective, arguments was that from the probable incommensurability of motions noted above. If some of the heavenly motions were incommensurable with each other, then the planets could never return simultaneously to exactly the same positions, and so any precise occurrence of a Great Year, implying a cyclical universe, was impossible. Oresme concluded his most developed treatise on the subject, the *De commensurabilitate vel incommensurabilitate motuum celestium (On the Commensurability or Incommensurability of the Heavenly Motions)* with a dream in which Apollo presided over a debate between Arithmetic and Geometry as to whether there is such incommensurability, but the dream vanished before Apollo was able to pronounce a definitive judgement. Thus, although Oresme had argued for the probability of incommensurability, he emphasised that even here there is no certainty.

Oresme morally condemned magic if it were indeed employing evil demons, but was also keen to show that many effects often accounted magical were in fact produced naturalistically. Ironically, astrology had often been used to give such explanations, but Oresme necessarily employed a variety of other strategies. Among these were appeals to perceptual errors, trickery and the large effects of small causes, but especially notable was the configuration doctrine discussed above, which could in principle account for a host of occult virtues and happenings that were otherwise inexplicable. Puzzlingly, however, Oresme makes little if any appeal to this doctrine in a group of works later than the *Tractatus de configurationibus qualitatum et motuum (Treatise on Configurations of Qualities and Motions)* and assigned by manuscript evidence to 1370. This has led some scholars to contest the dating, but perhaps more plausibly we should see it as evidence of an almost playfully sceptical tendency, revealed especially in Oresme’s later work: to elaborate in considerable detail an elegant and imaginative schema, but to conclude that in the end it may be no more than imaginary. A particularly renowned example of this (together with other examples less well-known) occurs in his *Livre du ciel et du monde (Book on the Heavens and the World)* of 1377. In the course of his commmentary on the French translation of Aristotle’s *On the Heavens* which he presents there, Oresme questions the standard view of a stationary Earth and presents very strong arguments in favour of its diurnal rotation, before famously concluding that:

> Everyone holds and I believe that [the heaven] is thus moved and not the Earth, ‘for God has established the orb of the Earth, which shall not be moved’, notwithstanding the reasons to the contrary, for they are persuasions that do not conclude evidently. But considering all that has been said, one could believe that the Earth is thus moved and not the heaven, and the contrary is not evident; and yet at first glance this seems as much or more against natural reason as all or many of the articles of our faith. And so what I have said in this way for diversion can be valuable for confuting and reproving those who would impugn our faith with reasonings.
>
> (*Livre du ciel et du monde*)

In this way, an enlightened but sceptical scientific attitude buttressed religious fideism.

List of works

Oresme, Nicole (1351-5?) *Algorismus proportionum (Algorism of Ratios)*, ed. M. Curtze, *Der Algorismus Proportionum des Nicolaus Oresme*, Berlin: S. Calvary & Co., 1868. (Latin text of the mathematical work on the algorithm of ratios. An English translation of Part I can be found in E. Grant, ‘Part I of Nicole Oresme’s *Algorismus proportionum*’, *Isis* 56, 1965: 327-41, reprinted in E. Grant, *Studies in Medieval Science and Natural Philosophy*, London: Variorum Reprints, 1981.)

Oresme, Nicole (1351-5?) *De proportionibus proportionum (On Ratios of Ratios)*, ed. E. Grant, *De proportionibus proportionum and Ad pauca respicientes*, Madison, WI: University of Wisconsin Press, 1966. (Latin text and English translation of a treatise concerning ratios and motions.)

Oresme, Nicole (1351-5?) *Ad pauca respicientes (To Those Who Reflect On a Few Things)*, ed. E. Grant, *De proportionibus proportionum and Ad pauca respicientes*, Madison, WI: University of Wisconsin Press, 1966. (Latin text and English translation of a treatise concerning celestial motions and the question of the Great Year.)

Oresme, Nicole (1351-5?) *De commensurabilitate vel incommensurabilitate motuum celestium (On the Commensurability or Incommensurability of the Heavenly Motions)*, ed. E. Grant, *Nicole Oresme and the Kinematics of Circular Motion: Tractatus de commensurabilitate vel incommensurabilitate motuum celi*, Madison, WI: University of Wisconsin Press, 1971.(Latin text and English translation of Oresme's most mature work on the question of the commensurability or incommensurability of the heavenly motions.)

Oresme, Nicole (1351-5?) *Quaestiones super Geometriam Euclidis (Questions on Euclid's Geometry)*, ed. H.L.L. Busard, Leiden: Brill, 1961.(Latin text and English paraphrase of questions loosely related to Euclid's Elements.)

Oresme, Nicole (1351-5?) *Tractatus de configurationibus qualitatum et motuum (Treatise on Configurations of Qualities and Motions)*, ed. M. Clagett, *Nicole Oresme and the Medieval Geometry of Qualities and Motions: A Treatise on the Uniformity and Difformity of Intensities known as Tractatus de configurationibus qualitatum et motuum*, Madison, WI: University of Wisconsin Press, 1968.(Contains Latin text and English translation of Oresme's principal work on his doctrine of configurations. Clagett also suggests a provisional chronological ordering of Oresme's writings.)

Oresme, Nicole (1360?) *Livre de divinacions (Book on Divinations)*, ed. G.W. Coopland, *Nicole Oresme and the Astrologers: A Study of his Livre de Divinacions*, Liverpool: Liverpool University Press, 1952.(Contains French text and English translation of one of Oresme's anti-astrological works as well as the Latin text of another earlier work.)

Oresme, Nicole (1370?) *Questio contra divinatores horoscopios (Question Against Horoscopic Divinators)*, ed. S. Caroti, *Archives d'histoire doctrinale et littéraire du moyen age* 43, 1976: 201-310.(Edition of Latin text of an anti-astrological question, the first part of a four-part work, probably to be dated to 1370.)

Oresme, Nicole (1370?) *De causis mirabilium (On the Marvels of Nature)*, ed. B. Hansen, *Nicole Oresme and the Marvels of Nature: A Study of his De causis mirabilium with Critical Edition, Translation and Commentary*, Toronto, Ont.: Pontifical Institute of Mediaeval Studies, 1985.(Edition of the second part of the four-part work just noted. It concentrates on naturalistic explanations of marvellous effects: the title is not Oresme's own.)

Oresme, Nicole (1372-4) *Le Livre de Politiques d'Aristote (The Book on the Politics of Aristotle)*, ed. A.D. Menut, *Transactions of the American Philosophical Society*, new series 60, Part 6, Philadelphia: American Philosophical Society, 1970.(French translation with commentary on Aristotle's *Politics*.)

Oresme, Nicole (1377) *Le livre du ciel et du monde (Book on the Heavens and the World)*, ed. A.D. Menut and A.J. Denomy, Madison, WI: University of Wisconsin Press.(Edition and English translation of Oresme's French translation of and commentary on Aristotle's *On the Heavens*.)

Orientalism and Islamic philosophy

Orientalism is the concept that there is something very special and different about the thought of those living in the East, which can be discovered through the methods of scholarship current in the West. It is a reflection of the relationship of imperial and intellectual domination of a West which feels it is superior to an 'inferior' East. This often results in an understanding of Islamic philosophy which sees the latter as essentially unoriginal, derivative and of only historical interest. While orientalists have produced interesting and important work, most fail to appreciate the independent status of the material which they analyse.

1 The notion of Orientalism

Orientalism is the branch of scholarship that uses traditional Western methods as a means of understanding and gathering knowledge pertaining to the Orient. The term was also used by Edward Said (1978) to elucidate his own challenge to the validity of such methods.

On the one hand, Orientalism has given us much of what we know about the Oriental world at large. Late nineteenth-century authors are especially worthy of consideration for their contributions to an understanding of foreign cultures and peoples. On the other hand, however, several problems arise from the attitudes and methods used in traditional Orientalist discourse, which in turn has had an impact - often negative - upon Western consciousness. This influences and distorts the framework through which the West approaches the Orient in general and Islam in particular.

The Orient encompasses a far greater area than simply that of the Arabs and the Muslim community; exotic images from India, China, Japan and Korea are conjured up in the minds of Western people when they think of the Orient. However, Orientalism has had a particular impact on the study and understanding of Islamic philosophy. Many scholars' understanding of Islamic philosophy is, 'that Islamic civilization as we know it would simply not have existed without the Greek heritage' (Rosenthal 1975: 14).

2 Orientalism as a political doctrine

Orientalism has several different but interrelated meanings. In its general sense, it describes the way in which the West looks at the Orient in order to understand it within the context of Western experience. More specifically, Orientalism is a categorical approach by Western scholars as an attempt to form a collective body of knowledge about the Orient. Included in this enterprise is the study of Eastern philosophies, history, religion, culture, language and social structures. To understand the effect of Orientalism on Islamic philosophy, however, we need first to understand it as a political doctrine; from its inception, Orientalism was primarily political and secondarily cultural and philosophical.

Orientalism as a system of the knowledge began in the late seventeenth century, reaching its zenith in the late nineteenth and early twentieth centuries. During this period Britain and France, and later the USA, were involved in the struggle for Western domination. This Anglo-French-American experience was essentially imperialistic. Implicit in the Orientalist attitude, therefore, is the belief that the Orient had passed its golden age as the West was being 'born', and was thus in decline. This view of the Orient as backward and barbaric led to interpretations which resembled more closely what scholars wished to believe, rather than what actually was the case. In philosophy, this attitude led to the belief that the entire system of Islamic philosophy was based upon the Greek inheritance; this in turn led to the belief that Islamic philosophers were not good Muslims, as philosophy and religion apparently could not be reconciled.

Along with this attitude, Orientalism also played an active role in advancing Western interests in the East. The pursuit of knowledge of the Orient was often not an end in itself. The study of Islamic philosophy merely confirmed many Western scholars in their belief of the superiority of their own culture.

3 The Orientalist approach to Islam

From the beginning, Orientalists have viewed Islam in two ways. First, as it had borrowed liberally from Abrahamic (Judaeo-Christian) traditions, Islam was considered to be a crude parody of Christianity. Second, Islam

was looked upon as an alien menace which historically had enormous military and political success throughout the world, and consequently was a threat to Western civilization.

In Orientalism, Islam first had to be placed within the realm of Western understanding with respect to Christian concepts rather than regarded on its own terms. One way of accomplishing this was to make analogies between Christian religions and Islam. The obvious parallel is the one which some Orientalists draw between Muhammad and Christ. Since Christ is central to the Christian faith, Westerners assumed that Muhammad holds the same place in Islam. This misconception helped to popularize the use of the name ‘Mohammedanism’, a term highly offensive to Muslims. The Christ analogy also served to reinforce the notion that Muhammad was nothing more than an ‘impostor’ and a pale version of the Christian Messiah.

Islam also provided a provocation to the West in another respect. From the time of the Arab conquests in the seventh century to the ascendancy of the Ottoman Empire, Islam itself posed a formidable challenge to the Christian world. Islamic empires - Arab, Ottoman or those in Spain and North Africa - had quite effectively challenged and, at least for short periods of time, dominated Christian Europe.

4 Orientalism and Islamic philosophy

The first wave of Muslim conquest in AD 632- 4 secured for the Arab Muslims the strongly Hellenized territories of Syria and Egypt along with the western part of the Sassanian Persian empire. At first the new conquerors may have been suspicious about the culture of classical antiquity, as both religion and language separated the Arab Muslims from the vanquished peoples. However, the former overcame their anxiety remarkably quickly and began instead a cultural conquest and assimilation of ancient knowledge.

Philosophers such as Ibn Sina, al-Kindi, al-Farabi and Ibn Rushd all interpreted the Islamic inheritance of classical philosophy and attempted an assimilation of it into mainstream Islam in their writings (see Aristotelianism in Islamic philosophy; Neoplatonism in Islamic philosophy; Platonism in Islamic philosophy). The classification of the sciences, in encyclopedic proportions, was carried out by the likes of al-Khwarizmi in his *Mafatih al-‘ulum*, and by a group of scholars in the ninth and tenth centuries who called themselves the ‘Brethren of Purity’ (Ikhwan al-Safa’). The attitude of these and other philosophers was one of acceptance and the transferring of intellectual history, rather than an adoption of so-called ‘foreign’ ideas. Many of these ideas were foreign indeed, as we do not see any mention of them in the Qur’an and earlier traditional works, but the underlying theme was the gaining and spread of knowledge, *‘ilm*. Gaining of knowledge is obligatory according to the tradition of Muhammad, the prophet of Islam, who said: ‘Seeking knowledge (*‘ilm*) is obligatory upon all Muslims, men and women.’

This approach is clearly brought out in the epistles of the Ikhwan al-Safa’ (see Ikhwan al-Safa’). During a lengthy debate in these epistles, between humans and animals in the court of the king of the *jinn*, examples from history are given in which the conquering nations took over, translated into their language and made their own the knowledge of vanquished peoples. Solomon is cited as a classic example:

> Our sciences and the sciences of all the nations are [acquired] one from the other. If this was not the case, from where did the Persians get astrology, astronomy and observatories? Did not they take it from the Indians? If it was not for Solomon, where did the Israelites get the sciences…. He took it from the kings of all nations when he conquered their territories and transformed them to Hebrew…
>
> (Rasa’il Ikhwan al-Safa’ 2: 288)

This transcendental open-mindedness has been misrepresented many times by Western scholars, who are more interested in finding something new in the Islamic sciences than in attempting to understand the transmission of the corpus of human knowledge from one people to another. The Orientalist outlook mentioned above appears clearly when scholars such as Walzer and Rosenthal expend much effort in finding faults within the Islamic philosophical system, rather than using their impressive abilities to develop a better understanding of the amalgamation and legacy that has been left by the Islamic philosophers. In Walzer’s important work, *Greek into Arabic* (Walzer 1962), the attitude is that everything the Arab philosophers had to say was ‘borrowed’ from the Greeks. Even when we are not able to find the source, according to Walzer, it can be assumed safely that the original Greek source is no longer extant.

This imaginary dichotomy between philosophy and theology, as assumed by the Orientalists, has led to a severe

crippling of the understanding of the achievements of the Islamic philosophers. This attitude itself has its roots in the initial reaction to the impact of Greek philosophy upon Christianity. Orientalist scholars assume that the Muslims felt exactly the same as the early Christians did about the conflict between philosophy and theology. Of course there were debates between Islamic philosophers and theologians, but in the Arab and Islamic milieu the attitude was rather different from that in the Christian world; in the former, the philosophers were simply taking what they assumed was their legitimate inheritance from the corpus of human knowledge.

In conclusion, these notions about the Orient eventually ‘created’ the Orient. The ‘Orient’ (East) is, in fact, only East from an European perspective: it is a relative, not absolute, term. More precisely, the ‘Orient’ is whatever the Orientalists say it is: it is a series of abstractions based upon Western-generated ideas rather than upon Oriental realities. Islamic philosophy needs to be studied as more than just a reflection of Greek ideas; it needs to be considered as an area of thought which came into contact with a variety of different cultures, and which developed out of these and out of a meditation on the Islamic sciences themselves into an independent and original form of philosophical thought.

Origen (*c.*185-*c.*254)

An ascetic Christian, prodigious scholar and dedicated teacher, Origen devoted his life to exploring God's revelation. Much of his work takes the form of commentaries on Scripture. He argued that Scripture has three levels: the literal, the moral and the spiritual. The literal level veils the others, and we need God's help to find the divine mysteries behind the veil. His commentaries directly or indirectly influenced the practice of exegesis throughout the patristic period and the Middle Ages.

Origen used his spiritual exegesis, as well as arguments, concepts and models drawn from philosophy, to tackle the theological problems of his day: the compatibility of providence and freedom, the relation of the Father, Son and Holy Spirit to each other and to rational creatures, the problem of evil, and the origin and destiny of the soul. He is famous - or infamous - for arguing that the souls of angels, demons and human beings enjoyed a previous heavenly existence, but that they sinned and fell. God created the world to punish and remedy their faults.

1 Life and works

Origen was born to Christian parents in Alexandria. When he was seventeen, his father was martyred in the persecutions of Septimius Severus. Origen, the oldest child, supported his family by teaching grammar. Shortly afterwards, Bishop Demetrius asked Origen to take charge of the catechetical school in Alexandria. In that time of persecution, such a charge meant preparing catechumens not only for baptism, but for martyrdom as well. Accordingly, in addition to teaching, Origen tended to the martyrs at their trials and in prison, and even accompanied them to their executions. He himself lived an ascetic life, sleeping and eating very little, devoting himself to teaching, study and pastoral work with an uncompromising intensity.

He studied philosophy in Alexandria, perhaps with Ammonius Saccas, who taught Plotinus. He read widely in Greek philosophy, but also studied Jewish writers, in particular Philo of Alexandria, and was conversant with rabbinical traditions. In Alexandria, he founded his own school of advanced study. However, at some time between AD 230 and 233, Origen fell from Demetrius' good graces and was banished from the church of Alexandria. Origen then moved to Palestine, where he enjoyed strong support from the bishops, and founded another school of advanced study. When the persecution of Christians resumed under the Emperor Decius, Origen was arrested, imprisoned and tortured. When the persecutions ended, he was released. He died shortly thereafter.

Origen wrote a prodigious number of works, some scholarly, some polemical, but all with the pastoral aim of helping Christians to avoid error and deepen their knowledge of moral and spiritual truth. In *Kata Kelsou (Against Celsus; known in its Latin translation as Contra Celsum)*, he defends Christianity against charges of irrationality levelled by the pagan philosopher Celsus. Origen's *Peri archōn (On First Principles)* is the first work of Christian systematic theology; however, acutely aware of his own fallibility, he proposes the elements of his system very tentatively. Origen also preached and wrote commentaries on nearly every book of Scripture, although most of these works have not survived and some exist only in Latin translations. It is impossible to overestimate the importance of these commentaries, whose methodology and content had a profound influence on Basil of Caesarea, Gregory Nazianzen and Gregory of Nyssa in the East, and on Jerome and Ambrose in the West (see Patristic philosophy). Through these writers, Origen influenced the practice of exegesis throughout the Middle Ages.

2 Revelation

In Origen's view, Christians can come to understand moral and spiritual truths through study of Scripture. The Holy Spirit revealed these truths to the apostles and prophets, who recorded them in their writings for the benefit of the faithful. However, to express these truths plainly would risk allowing the enemies of the Church to ridicule them. Consequently, the authors veiled these truths in narratives and legal ordinances which constitute the literal level of Scripture. To find the spiritual level, Origen uses typological and allegorical exegesis. Typological exegesis, practised before Origen by Justin and Irenaeus as well as by the authors of the New Testament, interprets passages in the Old Testament as foreshadowing something in the gospel, whether historical or spiritual. Allegorical interpretation, practised before Origen by Philo of Alexandria, understands every detail of Scripture to have a moral or spiritual significance.

Finding the spiritual meaning of Scripture requires more than philological skill. As Origen sees it, one must first lead the spiritual life, a life of devotion to Christ in prayerful and diligent study of the Scriptures. As one becomes more like Christ and participates in him, one becomes worthy to be taught the mysteries of the spiritual gospel hidden by the literal gospel. Christ himself must lift the veil from the letter. Origen supposes that Jews, Gnostics and literalists misread the Scriptures because they do not listen to Christ's explanation, available inwardly to those who lead the spiritual life. In his commentaries and homilies, Origen often prays for Christ's help, or asks his listeners to pray for him, so that Christ might lift yet more of the veil from the letter. This process will continue in the next life, where Christ will teach the blessed, face to face, more and more of the spiritual mysteries (see Revelation).

3 Theology

The prophets and apostles taught in plain terms only a small part of the spiritual gospel, including the most important truths: that God is one and the creator of the world; that his Son took a human body without resigning his divinity, and that he suffered, died and rose from the dead; that the Holy Spirit inspired the saints of both Testaments; that the rational soul is free and will be rewarded or punished according to its deserts. The apostles left the explanation and clarification of these truths to others who have received the gift of wisdom from the Holy Spirit. Origen's theology consists largely of what he takes to be this explanation and clarification. Acutely aware of the immensity of this task and of his own limitations, Origen often presents his views tentatively. With equal intensity and humility, he combs the Scriptures to investigate the relationship among the persons of the Trinity, God's motives in creation; the incarnation and resurrection, and the origin and destiny of human beings, angels and demons. For these investigations, Origen borrows concepts, models and arguments from various philosophical schools, including the Stoic, Peripatetic and, in particular, the Platonic schools (see Neoplatonism; Platonism, Early and Middle). Though he finds philosophical tools and speculations useful in the service of Christianity, he warns his students to give their allegiance to God and not to any philosophical school. Too often, giving allegiance to one school means closing one's mind to other ways of thinking.

In Origen's theology, God is a Trinity of three beings or hypostases: the Father, the Son and the Holy Spirit, coeternal, incorporeal and uncreated. Each of these three beings has its own attributes and role to play in the created world and in the life of the Trinity itself. The Father is absolutely simple, immutable and impassible. He receives nothing from any source, but is himself the source of all being and all goodness. The Son, begotten by the Father, bears the titles Wisdom, Word, Truth and Life, which characterize him as he is in himself, and about one hundred further titles which characterize his relationship to the created world, such as Redeemer, Good Shepherd and High Priest. The Holy Spirit sanctifies rational creatures, conferring spiritual gifts on them. The Spirit receives being and goodness from the Father, and wisdom and intelligence from the Son.

Origen's admirers and detractors alike express worries about his subordination of the Son and Holy Spirit to the Father. Only the Father is God in his own right; the Son and Holy Spirit merely participate in his Godhead, as they participate in his being and goodness. However, Origen never asserts that the Son and Holy Spirit are God or good to a lesser degree than the Father, only that they receive their Godhead and goodness from him.

The Father creates the world and everything in it *ex nihilo*, not from pre-existent matter. Origen sometimes proposes that the Father creates not just one world but a succession of worlds, though that series itself has a beginning in time. His denial of the eternity of this series makes him vulnerable to the criticism that God was idle before the creation. However, to think God idle is both inconceivable and impious. God so overflows with goodness and creative power that it is impossible for him not to exercise this power and to manifest his goodness. Recalling the verse from Psalms 104 (103), 'In Wisdom hast thou made them all', Origen speculates that in addition to the temporal creation, there is also an eternal creation: The Father eternally creates in the Son, whose chief title is Wisdom, the plans and patterns of the temporal world as an expression of his power and goodness. In the Son, then, exist the genera and species of all things, and perhaps the patterns for individuals as well. The Son, therefore, provides the link between the One and the many (see Trinity).

4 Rational creatures

Origen develops much of his thought about rational creatures by reflection on the problem of evil and the goodness of God (see Evil, problem of). He was impressed by the great inequalities of life: inequalities of power, privilege

and opportunity, of flourishing and suffering. Why are some rational creatures angels, some demons and others human beings? Why are some human beings born into power and privilege and others not? Why are some Christians martyred for their beliefs? The Gnostics claim, Origen writes, that some souls are by nature good, others evil, and still others indifferent, and one's lot in life depends on the nature of one's soul. Otherwise one's lot would be a matter of blind luck (see Gnosticism). Origen rejects this Gnostic view. God's providence governs every individual's life, so the inequalities of life cannot be due to luck. Moreover, because he is good and just, God would not introduce inequality arbitrarily and, therefore, unjustly.

Origen proposes that rational creatures enjoyed a pre-existent life, united to God in heavenly contemplation. God created them entirely equal and sinless. However, because they were rational, their actions were up to them; and because God created them out of nothing, they were mutable. Although Christ's human soul retained its innocence, other souls - perhaps all others - fell from their original union with God. Origen sometimes suggests that they grew satiated and lost interest in their contemplation of God. God responded to their fall by creating the world and assigning the fallen creatures a place in it according to their deserts. Those who distanced themselves from God the least became angels; those who distanced themselves the most became demons; and those whose fall was neither great nor small became human beings.

Human life, then, is God's punishment for sins committed in the pre-existence. The particular circumstances in which human beings find themselves - their advantages and disadvantages - are assigned to them according to their deserts. However, Origen finds God's punishment remedial as well as retributive. God is a doctor who sends us bitter medicine only to cure us. Origen also likens God to a loving tutor whose discipline aims at teaching the pupil a lesson. He puts us to the test because he wants us to face the secrets of our hearts: it is only through temptation that we see what we are really like. If we do not learn our lessons in this lifetime, then God does not abandon us, but continues the plan for our salvation into our next life (see Salvation).

From Paul's teaching that, at the end, God will be all in all, Origen formulates his account of the *apocatastasis*, or restoration, when rational creatures regain the purity of their original state and God fills their minds. In *Peri archōn*, Origen suggests that the *apocatastasis* will be universal, so that all rational creatures, even the Devil, will eventually turn to God. However, he has no settled view on this subject. In a letter to friends in Alexandria, he explicitly denies that the Devil will be saved, and his homilies on Jeremiah suggest that some human beings too will suffer eternal punishment.

Orphism

Orphism, a speculative trend within Greek religion, claimed the mythical singer Orpheus as founder and prophet. In changing forms, it is in evidence from the 6th century BC *to the end of antiquity. Hexameter poems were attributed to Orpheus, especially a theogony about the origin of gods, world and mankind, and sectarian groups led an 'Orphic life', practising mystery cults supposedly founded by Orpheus. The main goal was salvation of the soul from evil, traced to 'ancient guilt', with a view to a blessed existence after death; this usually included the doctrine of transmigration*

Myths about Orpheus, son of the Muse Calliope and a Thracian called Oiagros, are in evidence from the sixth century BC and current in the fifth. Orpheus, a lyre-player and singer, is said to have taken part in the expedition of the Argonauts. He enchants even animals with his music. He descends to the netherworld to get back his wife Eurydice, an attempt that fails. Although torn to pieces by Thracian bacchants, his severed head continues to sing and to give oracles.

A theogony is attributed to Orpheus, the key document of which is a fragmentary papyrus book, unearthed at Derveni in 1962, containing quotations and allegorical commentary on Orpheus' text (see Most and Laks 1977). The theogony begins with 'Night', from which a series of 'kings' of gods springs: Uranos (Heaven), Cronos and Zeus. Zeus, after a strange incident of 'swallowing' a 'phallus (?)', brings forth the other gods from himself and proceeds methodically to establish the world. Then, by incest with his 'Mother', he begets a further offspring, Persephone, leading towards the creation of mankind.

The Derveni text ends here. Plato alludes to Orpheus' theogony, which comes to a stop 'in the sixth generation' (Dionysus as the father of man?). He attests that, according to the teachings of Orphics (*Orphikoi*), the soul is incarcerated in the body during this life to be punished for certain unspeakable crimes. The corresponding myth is traceable through much-debated allusions in older texts, but becomes explicit in later sources: mankind rose from the soot of the Titans, burnt by the lightning of Zeus after they had treacherously killed and eaten the child Dionysus (also called Zagreus), son of Persephone and Zeus; hence the sufferings, the warning against falling back into the 'old Titanic nature', and the yearning to get rid of the 'unlawful forefathers', 'to reach the end of the cycle, and to take breath from evil'. The means towards this are ritual purifications and the adoption of a 'pure' life, the 'Orphic life', characterized above all by vegetarianism. There are special myths about the judgment of the dead and punishments or blissful existence in the netherworld, and a belief in transmigration, with repeated chances of personal guilt and atonement in successive lives. Transmigration, together with certain taboos, constitutes an overlap with Pythagoreanism (§3). This makes it impossible to decide exactly what role Orphic literature and teaching played in the emergence of the concept of a personal 'soul', or *psychē* (see Psychē), independent of the body and antithetical to it, before Plato's philosophical restatement of this theory (see Plato §§10-13).

Other evidence is the gold lamellae found in tombs of southern Italy, Thessaly, Lesbos and Crete (see Pugliese Carratelli 1993 for a partial translation of the evidence). Dated from the late fifth to the second century BC, these bear instructions for the dead on how to pursue their way towards bliss in the beyond. The texts differ in length and in specific details, but still form an interlocking whole. As they refer to 'bacchants and initiates' (Hipponion, southern Italy) and to the 'release' wrought by Bacchios, that is, Dionysus (Pelinna, Thessaly), they clearly presuppose rites of Dionysiac or 'Bacchic' mysteries, spread by travelling initiation priests. The initiate may proclaim his identity as 'son of Earth and starry Heaven'; there is the prospect of Elysian life, after drinking from the 'lake of memory'; there also occurs the declaration 'you have become god instead of a human'; in addition, there are suggestive but enigmatic formulae such as 'kid I fell into the milk'. The reference to transmigration is opaque, and that to Orpheus is not explicit, but Orphism remains the most probable context.

Orphics, in connection with Dionysus and with dualistic speculation about 'soul-body' and 'life-death-life', also are attested at Olbia in the fifth century BC. Instructions for practical mysteries are found in an Egyptian papyrus text from the third century BC (see Kern 1963: fr. 31).

In Hellenistic times, the theogony of Orpheus went through various conflicting versions and expansions. Oriental influence can be discerned in the striking predilection for grotesque mixtures of images. 'Unageing Time'

(*Chronos ageraos*), for example, appears in the form of a three-headed snake, with the heads of a bull, a god and a lion. The main text had 'Time' (Chronos) for the primeval god, hatching an 'Egg' from which the world was fashioned. The Egg then broke in half to release a mysterious god of light, Phanes, also called Erikepaios (an unexplained) and identified with Dionysus. At a later stage, Zeus swallowed Phanes and everything else in order to recreate the whole of the world from himself; here one can trace Stoic concepts and terms about the 'sympathy' of the universe (see Posidonius §5). This theogony became a reference text for Neoplatonic philosophers until the end of paganism, from Porphyry to Proclus and Damascius. A revelation of polytheism more serious than those of Homer and Hesiod, it was adapted to Platonic ontology by allegorical interpretation. There is also a collection of 'Hymns of Orpheus', stemming probably from a sectarian community in Asia Minor, which testifies to the ongoing practice of Orphic cults in the imperial age (see Quandt 1952).

By contrast, long before, in the third century BC, a 'Testament of Orpheus' had been fabricated. Reflecting contacts with Judaism, it sets out to counter the Orphic theogony. In it, Orpheus revokes polytheism and proclaims the one god, creator of the universe. This was used by both Jews and Christians to rebuke paganism (see Riedweg 1993 for a detailed discussion).

Ortega y Gasset, José (1883-1955)

The Spanish philosopher Ortega borrowed themes from early twentieth-century German philosophy and applied them with new breadth and urgency to his own context. Calling his philosophy 'vital reason' or 'ratiovitalism', he employed it initially to deal with the problem of Spanish decadence and later with European cultural issues, such as abstract art and the mass revolt against moral and intellectual excellence. Vital reason is more a method for coping with concrete historical problems than a system of universal principles. But the more disciplined the method became, the deeper Ortega delved into Western history to solve the theoretical and practical dilemmas facing the twentieth century.

1 Life

Typifying liberal Spanish philosophers of the late nineteenth and early twentieth centuries, José Ortega y Gasset philosophized in order to reverse Spain's historical decline. Born into two publishing families, he achieved eminence as a philosopher-journalist, an educator, and in 1931 as a politician. Postdoctoral studies in Germany acquainted him with Neo-Kantian philosophers of culture Georg Simmel and Hermann Cohen (see Neo-Kantianism). From Cohen's follower Paul Natorp, Ortega learned of Husserl's phenomenology, which he introduced into Spain in 1913 in newspaper articles, three years after obtaining the Chair in Metaphysics at the University of Madrid (see Husserl, E.; Phenomenological movement). His first book, *Meditaciones del Quijote (Meditations on Quixote)* (1914), employs phenomenological descriptions in essays on the salvation of Spanish culture by means of Cervantes' insights. Among journals Ortega founded, the most distinguished, *Revista de Occidente (Review of the West),* begun in 1924, informed Spaniards of innovations in philosophy, anthropology, physics and art. Ortega phenomenologically analysed avant-garde art in his renowned *La deshumanización del arte (The Dehumanization of Art)* (1925). He sensed significant progress being made in saving Spanish civilization through rigorous concepts.

Yet the following eleven years offered little cause for optimism. In 1929, intervention in university affairs by the dictator Miguel Primo de Rivera prompted Ortega to resign his Chair. Renting theatres, he offered a Bergson-style public course, *Čiquest;Qué es filosofía? (What Is Philosophy?)* (1929-30), in which he unveiled his mature principles of human existence. In 1930 Ortega's best-known book appeared, *La rebelión de las masas (The Revolt of the Masses)*, launching a philosophical attack on an over-egalitarian age for aggrandizing mediocrities such as Primo and Mussolini. During the Second Spanish Republic (1931-6), Ortega founded a party of intellectuals. While an elected Member of the Spanish Parliament, he deplored extremism of right and left, only to abandon politics himself in 1932 and leave the country in 1936, before civil war erupted.

In 1945 he returned to Franco's Spain, but the hostility of Church and State drove him to lecture abroad whenever possible in his final years. In his richest, most rigorous work, the posthumous *La idea de principio en Leibniz y la evolución de la teoría deductiva (The Idea of Principle in Leibniz and the Evolution of Deductive Theory)* (1946-50), he rebuts hostile clerics. To Spain and Spanish America he bequeathed an elegant and precise philosophical vocabulary, along with a number of outstanding students, notably Xavier Zubiri and Juan David García Bacca.

2 Relations between reason and life

The problem of the relationship between reason and life lies at the root of Ortega's thinking. Both terms vary in meaning as his method of 'vital reason' matures, the variations stemming from his dialogues with contemporaries. He corresponded with the older philosopher Miguel de Unamuno, who, with Kierkegaard and Liberal Protestant theologians, conceived authentic existence as the struggle between reason and life: life affirms immortality after death; reason denies it. But Ortega dodged religious issues to concentrate on the philosophy of culture. In Georg Simmel he found an opposition posited between life as process and life as cultural principle, with authentic culture a synthesis of both. Hence in *El tema de nuestro tiempo (The Modern Theme)* (1923), Ortega wrote, 'Life should be cultured, but culture must be vital'. Simmel's notion of life as process, a continual becoming, drew Ortega close to Nietzsche, Bergson and the Darwinists (see Vitalism). Yet Ortega found a more fruitful idea in Cohen, who held that, to be oneself, it is necessary to use logic, such as the induction and deduction employed in mathematical physics. Ortega embraced the conception of life as a search for identity, but qualified Cohen's emphasis on

scientific logic: for Ortega, the problem of personal identity stands in the foreground, and the solution of physico-mathematical logic only at midground. Therefore, from 1910, Ortega's point of departure became the idea of life as a problem of self-authentication, but without Cohen's faith in the constructs of scientific reason as a solution to it.

Ironically, it was Cohen's fervent follower Natorp who drew Ortega's attention to other forms of reasoning, by alerting him to the strengths and weaknesses of Husserlian phenomenology. Before 1907, Husserl had stressed the cognitive value of the direct contemplation of essences called 'intuition' (*Anschauung*): I can 'intuit' an apple, the colour red, a circle, a mythical fruit. From 1907 on, however, Husserl stressed that 'pure' intuition requires self-conscious reflection, and Natorp argued that reflection is a mental construct, mediating between mind and object and thereby preventing the pure intuition of essences. Natorp's objection would recur from 1914 to 1950 in all Ortega's discussions of Husserl. However, Ortega incorporated into his own thought a modified version of the unmediated intuition of the pre-1907 Husserl. 'Vital reason' is most concisely formulated in the phrase, 'I am myself and my circumstance'; according to Ortega, I am a self-aware interaction with my concrete surroundings, a repertory of possibilities which my intuitive reason helps me realize. The word 'circumstance', as employed in 1914, also connotes Ortega's homeland. So, unlike Unamuno, who perceives an irreconcilable clash between reason and life, Ortega applies Husserlian intuitive reason to resolve problems of national life or 'circumstance'.

Ortega's thinking on life and reason deepened in 1929. Reading the work of Husserl's student Heidegger in 1928 helped Ortega to organize his earlier philosophy into the four principles first formulated in *What Is Philosophy?*: (1) my life is the 'radical reality', the framework in which all other realities (including reason) appear; (2) my life is a self-conscious problem of individual realization; (3) my problem amounts to deciding among specific possibilities for self-authentication; (4) the plurality of these possibilities defines my freedom in life; their quantitative finiteness, my limitation. But, rejecting Heidegger's ontological jargon, the mature Ortega adopted the life-centred lexicon of Wilhelm Dilthey, whose philosophy of history Ortega read thoroughly in 1928. Thus emerged the last step in the evolution of 'vital reason', its absorption of what Dilthey called 'historical reason'. Ortega's third basic principle defines life as decision among possibilities, but what determines the decision, according to Dilthey, is a generational worldview (*Weltanschauung*), a system of subrational beliefs. Narrating the beliefs guiding great decisions can solve cultural problems.

What, therefore, is 'vital reason' as method? First, the posing of a current philosophical problem; second, phenomenological reduction of the problem; finally, narration of historical causes of the problem so as to solve it in practice. The structure of Ortega's most concise book illustrates this - *Historia como sistema (History as System)* (1935). Here he poses the problem of the loss of faith in scientific reason, because it is felt to be incapable of defining human being. How then should one reorient humankind in the universe? Phenomenological reduction prescribes the suspension of historical forejudgments, ascent to universals, descent from universals to essences, and description of essences. So Ortega suspends the historical forejudgments, received from the natural sciences, that humans have a nature, a changeless substance knowable with scientific logic. He also dismisses ideas of humans as body or psyche, since he regards such ideas as naturalistic. Instead, he finds that the 'radical reality' of each human being is precisely the life of that individual, and he describes that existence by enumerating its main aspects: its self-consciously problematic quality, the capacity for making decisions from among possibilities, and the limitations on these possibilities. Since historical reason can explain the decision-making, history is the discipline which will orient human beings in the universe by narratively clarifying their beliefs, defining them and instructing them in past errors to avoid such errors in the future. In proof, Ortega narrates the history of the West, in which belief in God gave way to belief in nature (whose study is natural science), and once scientism faltered, there arose belief in nothing but disillusionment, the science of which is history.

3 Works

Ortega's production exceeds the dozen volumes of over 500 pages each in the *Alianza* edition of his *Obras Completas*. Like Simmel and Max Scheler he addresses a vast thematic spectrum; let us summarize, first, his most translated work, *The Revolt of the Masses*, and, second, his *Leibniz* book, the one most deserving of philosophical attention.

Like all his major writings, *The Revolt of the Masses* begins with the posing of a current issue: why do the masses demand space in cultural sites once reserved for the moral and intellectual elite? Ortega dismisses as historical

forejudgments all political and economic explanations. Instead, he accepts what for him is a self-evident universal: an idea of society as dynamic interaction between moral and intellectual minorities and multitudes. Out of these two pure human types - elites and masses - Ortega derives a definition of the then-current mass type: a hybrid, it combines the great potential of the elite with the inertia of the mass type of bygone eras. Though powerful, the masses of the 1930s create nothing and even rebel against the elite, which does in fact create. The revolt evinces cultural strengths - the rise in the quality of life, the adventure of living in a dangerous era, the growth of personal possibilities - but even greater weaknesses - mass aggressiveness in public affairs, opposition to liberalism, obliviousness to history, overspecialization, excessive reliance on the state, and historical demoralization. Ortega proposes as a panacea the formation of a 'United States of Europe'.

From 1946 to 1950, he penned his Leibniz book in response to intellectually rebellious 'mass-men' - Spanish and Mexican Neo-Thomists who wrongheadedly criticize his mental style as metaphorical, overly dependent on sensory evidence and lacking stable principles. In 1946, on the tercentennial of Leibniz's birth, he posed a central problem: why, after formulating many philosophical principles, did Leibniz treat them so lightly? The implication was that the playful Ortega was in some way akin to the rigorous Leibniz, and this conclusion emerges along with the corollary that Ortega's foes themselves lack rigour and principles. Using 'historical reason', he shows that Aristotle, the father of Neo-Thomism, displayed excessive dependence on the senses, inexactness and inconsistency in handling principles. Ortega divides all philosophers into the disciplined, principled variety, based on intuition and not the senses (Plato, Descartes, Leibniz, Husserl, Dilthey and Ortega) and the less 'principled' type (Aristotle, the Stoics, the Schoolmen, Kierkegaard, Ortega's rivals Unamuno and Heidegger, and his detractors, the Neo-Thomists). 'Aristotelians' tend towards sombreness, anguish, inimical to genuine philosophy, while the Presocratics and Plato likened philosophizing to riddle-solving or participating in sports and games. This attitude, Ortega feels, confirms his distinction between rational ideas and subrational beliefs; humans act upon ideas or mere theories without ultimate seriousness, while beliefs act upon humans and are taken seriously. Therefore Ortega's apparent non-seriousness, like Leibniz's, does not negate his discipline. He confesses early opposition to Unamuno's tragic sense of life, the clash between reason and life, by speaking of a 'sportive and festive sense of existence', which implied an intellectual sportsman's endeavour to harmonize life and reason. 'Vital reason' is no more deficient in principles than the philosophies of Plato, Husserl and Dilthey. Ortega, one of the twentieth century's greatest essayists, deserves recognition as a brilliant transitional philosopher, bridging Husserl's phenomenology and Heidegger's ontology of existence with his own four principles.

Oswald, James (1703-93)

James Oswald, Scottish theological writer, used the philosophy of 'common sense' to try to found religious and moral conviction on principles that were impervious to scepticism. In a long running controversy over Church discipline, he defended the right of individual parishes to choose their ministers, seeing the prevailing system of patronage as favouring the advocates of a fashionable kind of civility that was too tolerant of scepticism and intellectual innovation, and too indifferent to the Church's traditional concerns with public and private morality. Though never part of the Aberdeen philosophical community, Oswald corresponded with Reid, and late in life collaborated with him in charitable work for the sons of clergy.

James Oswald was born at Dunnet in Caithness, where he succeeded his father as parish minister in 1726. He moved to Methven, Perthshire, in 1750, ministering there till 1783. He was Moderator of the General Assembly of the Church of Scotland in 1765, when he was awarded an honorary doctorate at Glasgow. As early as 1732, reporting to the Caithness Presbytery on a colleague's conduct, Oswald cited 'the common sense of mankind' to determine the binding character of promises. In *Submission and Obedience* (1753) he used the same authority to justify seeing the institutions of government as part of the divine plan for the world, arguing that the Church's mission could only be accomplished on the assumption that it too operated according to comparable principles of good order and government. From these derive obligations to duty, both civil and religious, which are 'obvious to the Understanding of Men'. This is reminiscent of George Turnbull's contention in his *Philosophical Enquiry* (1726, published 1731) that whatever is fit and binding in individuals' relations with one another and with God can be known by common sense (see Turnbull, G.). Turnbull and Oswald were products of the same divinity school at Edinburgh; they also shared a view of miracles as law-governed events.

'Common sense', meaning a direct deliverance of our common human reason or cognitive faculty, was cited by Oswald to justify practices the abandonment of which would undo social institutions, affront conscience or undermine religion. He subsequently extended it to cover all beliefs a challenge to which could be considered destructive of sense or sanity. Wherever the self-evidence of common-sense judgments was impugned, some form of incoherence (social or intellectual) would ensue. The commonest way of seeming to impugn them was to allow that they needed, or were even capable of, reasoned justification. On the contrary, they were held to constitute the primary truths which all reasoned justification must already assume (see Common sense school).

Oswald was unperturbed at the diversity of principles to which he accorded common-sense status, and in *An Appeal to Common Sense* (1766-72) resisted any attempt to give a precise analysis of this status or rest it on more formal criteria. The thread holding his primary truths together is that they had virtually all been targets of Hume's scepticism (see Hume, D.). Oswald commended Hume for seeing they are beyond the scope of reasoning, but he equated this too narrowly with strict demonstration, and argued against Hume that neither custom nor sentiment, both of which he considered highly fallible resources and the roots of bigotry and folly, could account for the transparent certainty of these unreasoned truths. Some degree of mental maturity, intelligent observation, even repeated experience, may be necessary to our initial appreciation of them, but thereafter their 'self'-evidence exceeds any other evidence we could cite for them. Oswald also criticized Francis Hutcheson and Henry Home for placing moral perception in feeling rather than cognitive judgment, but he agreed that moral training proceeds more by engaging the heart than the intellect (see Hutcheson, F.; Home, H. (Lord Kames)).

Oswald's primary truths fluctuate between the particular and the universal. They include beliefs with regard to our own existence and continued identity; the existence, identity and relative placings of objects around us and their motions, powers and causal operations expressed in the laws of nature; the existence of other sentient life with powers of action and traits of character; mathematical axioms; the being and providence of God; the real distinction between vice and virtue and its enforcement through punishment and reward; and the existence of obligations to God, others and ourselves. These are topics too central to this life and the next to be left to the rarified argumentation of the learned, and Oswald supposed it inherently ridiculous that the intelligent multitude should remain in suspense on them. A certain amount of unacknowledged chauvinism entered into Oswald's characterization of this multitude, whom he tended to see reflected in the persons of property and judgment who formed the mainstay of the Church of Scotland.

The laws of nature, for Oswald, are not formal, mathematical laws, but such relatively nebulous principles as that bodies sink by virtue of their weight, or that fire has the power to consume combustible materials. He means that the gravity of bodies and the power of fire are too much facts of life to be subject to caveats of inductive logic. In arguing that God's existence is evident to common sense, he wishes to avoid the metaphysical nicety of a priori demonstration and the inductive hazards of argument by analogy. To detect design, even on a limited scale, in inanimate nature is no different in principle from recognizing it among animals and humans, which in turn is no different (notwithstanding Hume's argument to the contrary) from actually experiencing the powers of things in their manifestation; and once Oswald has reached this point he develops his argument beyond the strict requirements of common sense philosophy, into a general theodicy.

Oswald's *Appeal* was sympathetically received in *The Monthly Review*, and by the Dissenter William Enfield in a tract directed to Joseph Priestley (see Priestley, J.). Philip Skelton commended Oswald's argumentative skill but thought he undervalued revelation. Favourable notices in *Göttingische Anzeigen* led to a German translation (1774), but the popularity of Oswald's work was shortlived. Priestley (1774) condemned his declamatory rhetoric, his restricted understanding of 'reason', and his dogmatic use of 'common sense' as an arbitrary block to legitimate enquiry. The translator of Claude Buffier's *First Truths* (1780) (see Buffier, C.) thought Oswald grossly over-extended the scope of common sense, and that he failed to see how often he was describing what were implicitly reasoned judgments.

Other Minds

It has traditionally been thought that the problem of other minds is epistemological: how is it that we know other people have thoughts, experiences and emotions? After all, we have no direct knowledge that this is so. We observe their behaviour and their bodies, not their thoughts, experiences and emotions. The task is seen as being to uncover the justification for our belief in other minds. It has also been thought that there is a conceptual problem: how can we manage to have any conception of mental states other than our own? It is noteworthy that there is as yet no standard view on either of these problems. One answer to the traditional (epistemological) problem has been the analogical inference to other minds, appealing to the many similarities existing between ourselves and others. This answer, though it is no longer in general favour among philosophers, still has its defenders. Probably the favoured solution is to view other minds as logically on a par with the unobservable, theoretical entities of science. That other people have experiences, like us, is seen as the best explanation of their behaviour.

1 What generates the two problems of other minds?

The epistemological problem arises from two facts. We lack direct knowledge of the mental states of other people. We have such knowledge of at least some of our own mental states. Put the two claims together and we have the traditional problem of other minds. The relevant asymmetry, between our own case and that of others, turns on the question of direct knowledge, not observation. Being able to observe the mental states of others would not enable us to avoid the problem. What would be needed would be the ability to observe those mental states as the mental states of others. They would have to come labelled. The situation would only then be symmetrical. We would have the direct knowledge we lack.

The same asymmetry generates the conceptual problem. How can we have the concept of other people's experiences given that we have direct knowledge only of our own experiences, labelled as our own? Once again, the problem is not that we cannot observe the pains of others. What would be needed would be observing such pains as, indeed, the pains of others.

There has been comparatively little discussion of the conceptual problem, and no more will be said here about the conceptual problem of other minds, other than to note that solving it would not, other than controversially at best, remove the epistemological problem. That problem will be hereinafter the one to be discussed.

2 Who has the epistemological problem?

The heroic way of avoiding the problem of other minds is to deny that the claimed asymmetry, between ourselves and others, holds. Some have done so by insisting that we have direct knowledge of the mental states of others, though this has generally been seen as implausible. However, there seems to be an important strand of thinking within feminist theory that would endorse this rejection of our asymmetry (see Feminism and psychoanalysis). Similarly, continental European philosophy has commonly taken the view that other people are needed for us to acquire our own sense of ourselves as persons (see Alterity and identity, postmodern theories of). So our sense of others goes before our sense of self. That would seem to demand some capacity to know about others before one knows about oneself. The asymmetry would, presumably, be reversed, and the problem of other minds give way to the problem of our own minds.

Given that the asymmetry is accepted, and thus the traditional understanding of the problem of other minds, it has been almost a commonplace to believe that only a traditional dualist view of the mind produces a difficult problem of other minds (see Dualism). Though generally theories of mind accept the asymmetry, not all are thought to have a difficult problem. Behaviourism (see Behaviourism, analytic) is a theory of mind that either is thought to have no problem at all, or, if it does, nevertheless has no difficulty in solving the problem. There is no special problem about knowing about the behaviour and behavioural dispositions of another.

Functionalism is another theory of mind that is thought not to have a difficult problem. Mental states are viewed as internal states of the organism, regulating its responses to its surroundings. The various mental states are differentiated by their various roles, and they have no other features relevant to their being the mental states they are (see Functionalism). It is then claimed to be straightforward, faced with the behaviour of others, to infer that

such internal states exist, in the appropriate relations to the behaviour. Eliminative materialists have been seen as not having any problem. If there are no minds, then there are no other minds, therefore there is no problem of other minds (see Eliminativism).

However, it has been argued that all theories of mind leave the other minds problem intact, and difficult. Theories of mind are, indeed, theories of mind, all minds, one's own and others. Given that they are to be true of all minds, including other minds, they cannot, it has been argued, be used to show that there are, indeed, other minds. It is unacceptable to argue that, say, functionalism is true, and then use this to solve the other minds problem, since it cannot be known to be true, to hold of minds in general, unless it holds of other minds. How could that be known without the other minds problem having been, somehow, solved?

In conjunction with this line of argument, it has been pointed out that a theory of mind, embracing all minds, needs to embrace its propounder's mind as well as other minds. So a crucial part of the evidence (generally implicit) for a theory of mind will be that the theory fits the propounder's experience. That is the only way direct evidence in its favour can be obtained. So the propounder's experience is crucial. It has been argued that there is no escaping dependence on that experience and, as we shall see, any such dependence has been seen to be a fatal weakness, whenever it exists, in any would-be justification for belief in other minds.

3 The analogical inference to other minds

The traditional solution to the problem of other minds has been the analogical inference to other minds. Other people behave like me in similar circumstances and have the same physico-chemical composition. When I burn myself it hurts and I cry out and wince. When other people are burned they cry out and wince. I can thus infer that they are in pain too. More generally, others are very like me. I know I have beliefs, experiences and emotions. So I am entitled, given how like me they are, to infer that other people also have beliefs, experiences and emotions.

This traditional analogical inference to other minds is now generally incorporated in a hypothetic inference (scientific inference, inference to the best explanation) to other minds. That there are alternative hypotheses about others which have to be ruled out requires that the argument take the form of a hypothetic inference (see Inference to the best explanation). But the appeal to one's own case, and to similarities, remains crucial in this analogical/hypothetic inference.

That, indeed, one's own case is crucial, gives rise to the classical, continuing objection to the analogical inference to other minds, that it is a generalization from one case. Such generalizations are almost invariably unsound. Though there have been attempts to put the analogical inference to other minds in a form that avoids this objection, it is generally accepted that such attempts have not succeeded.

However, its supporters argue that, even so, the analogical/hypothetic inference remains a sound inference, despite its dependence on one case. More than one case is needed where what is at issue is the question of a causal link between events. Where it can be known from one case that there is such a causal link, that one case will then be enough. It is claimed that the relevant causal link, involving mental states, can be known to hold from one's own case. Though it has traditionally been insisted that the relevant causal link is between mental states and behaviour, it has been urged that the relevant causal link needs to be between brain states and mental states if the analogical/hypothetic inference is to be defensible.

The other classical objection to the analogical inference to other minds has been that its conclusion was impossible to check, not just in fact, but in principle. This feature no longer seems to be seen as having any epistemological relevance.

4 Other minds as theoretical entities

This is probably, among Anglo-American philosophers, the favoured solution to the problem of other minds. The justification is in the form of a hypothetic inference. That others have mental states is hypothesized to account for how they behave. However, one proceeds purely from the outside. No evidence gathered from one's own case is used to support this hypothesis. The one case objection thought widely to be fatal to the analogical inference is, crucially, avoided, so it is widely believed.

It is generally considered that treating other minds in this way, as theoretical entities, will succeed if one has a

functionalist (or some such) view of the mind. The two seem made for each other. However, the argument in §1, that no theory of mind has an advantage over any other in supporting belief in other minds would, if successful, apply to this particular attempt to avoid dependence on one's own case.

It has been argued, conversely, that unless one enlists the help of a functionalist (or some such) theory of the mind, treating other minds as theoretical entities will not succeed. A traditional view of mental states, allowing that they have intrinsic content - in particular, phenomenal properties, such as the hurtfulness of pain (see Qualia) - cannot be supported by this method. Treating the mental states of others as theoretical entities, it is argued, will not provide those states with the needed intrinsic properties. That content can only be filled in by an appeal to one's own case.

5 Criteria and other minds

Treating other minds as theoretical entities, though an alternative to the analogical inference, takes the form of a hypothetic inference. Criterialists, by contrast, have sought to avoid the one case problem by eschewing any form of inference. They have insisted that the link between behaviour and mental states is neither entailment (as in behaviourism) nor an inductive inference. The link is claimed to be conceptual and such links are characterized as criterial. Behaviour is a criterion for the presence of mental states. It has been claimed by some that such a non-inferential connection is required if we are to have any concept of the experiences of others.

An example of such a claimed non-inferential link would be the claim that itching is conceptually linked to scratching, not merely contingently correlated. Our concept of itching is that it disposes one to scratch. It is further claimed that scratching is, thereby, evidence of itching, given that itching disposes one to scratch.

That there are such conceptual links has been widely argued and widely denied. That, if there are, they would provide a sufficient basis for belief in the mental states of other people has been, if anything, even more vigorously contested. The thrust of the attack on the use of criteria to support belief in other minds seems to be that such conceptual links fail to bridge the gap between observed behaviour and the unobserved inner states to which they are conceptually linked. If there is no entailment directly from the one to the other, and there is no appeal to some form of inductive inference, it is argued that we are left with the gap. The gap cannot be crossed by *fiat*, as it were.

One way of understanding what has been called the attitudinal approach to other minds, is to see it as going beyond other uses of criteria in insisting that our conception of other human figures is that they are souls, have experiences. That is how we perceive them. It is as immediate as that, preceding any belief. This criterial view seems, however, to inherit the criterial gap. However we conceive of reality, our conceptions might be mistaken. There are attitudes to things and people which, though more immediate and deeper than inferential belief, are, nevertheless, mistaken (racist and sexist attitudes might be given as instances).

6 Private language and other minds

It has been widely accepted that language is a public phenomenon. Some have insisted that it is essentially public. One way of understanding this claim is classically associated with Wittgenstein. A language that is necessarily private, that is, such that only one person can understand it, is (logically) impossible (see Private language argument).

The connection with the problem of other minds has been controversial. However, it seems clear that the connection exists in the reason given for the impossibility of such a private language. That reason bears directly on the analogical inference to other minds.

A necessarily private language is claimed to be impossible because a language has to be, in principle, subject to checking by someone other than an individual user of the language. Generally, a user of the analogical inference to other minds is in breach of this principle. They have insisted that each of us knows what psychological terms mean (at any rate, some of them) from our own case and only from our own case. Their usage would not then be, in principle, one that could be checked for consistency. Functionalists, by contrast, make no such claim, and it should be noted that the connection from private language to other minds depends on the use of terms whose meaning would be private in the relevant sense. The connection is not directly to any particular argument to other minds.

The argument that a check is needed (in principle, so Robinson Crusoe is not in trouble) has generally been that, in

its absence, no distinction can be made between its seeming to the language user that their usage is consistent, and its being so. They have only their impression to go on. The issue has been vigorously contested.

That a private language is impossible has not generally been used explicitly as an argument for other minds. Nor could it be. After all, it is only in principle that a language is to be checkable by other people. An important, though indirect role, however, could be seen as its supporting the criterialist insistence on the need for a conceptual connection between inner states and publicly observable states (see Criteria).

Otto, Rudolf (1869-1937)

Rudolf Otto, an early and leading student of religious experience, was a devout Christian thinker (part theologian, part philosopher, part phenomenologist of religious experience) who was strongly influenced by the philosophy of Immanuel Kant. He held that numinous experience - experience of the uncanny that is strongest and most important in cases in which it seems to its subject to be experience of God - is unique in kind. Such experience of God, he held, occurred in both Semitic and South Asian monotheistic traditions. Recognizing the intellectual or doctrinal content of numinous experience, but influenced by Kant's thesis that knowledge-giving concepts cannot refer beyond possible objects of sensory experience, Otto tried to remain faithful to both numinous experience and Kantian philosophy by talking about 'ideograms' that express the content of numinous experience but, allegedly at least, are not concepts.

Rudolf Otto was born into a devout Lutheran family in Peine, Hanover. Between 1888 and 1891 he studied theology in Erlangen, Göttingen and Bavaria. In 1891 he returned to Göttingen, where he became acquainted with Ritschlian theology. He received his licentiate in theology there for a study entitled 'Spirit and Word According to Luther', and was appointed a *Privatdozent* in 1899. He became Professor of Systematic Theology in 1904, a post which he also held in Breslau (1914-17), and in Marburg from 1917 until his retirement in 1929. He travelled widely in Egypt, Palestine, Greece, North Africa, India and the Far East. He learned Sanskrit and was an early figure in the effort to make South Asian and Indian thought accessible to a European audience. Otto was a pioneer in the history and phenomenology of religion, and the author of profound studies of mysticism, Śaōkara, Meister Eckhart, India's religions and the kingdom of God. The present entry will focus on his view of religious language and his account of numinous experience.

Otto, influenced by Kant, denied that concepts apply to God. But he also asserted the fundamental importance of doctrines about God and contended that it is possible for human beings to experience God. Kant had claimed that no concept could apply, in such a way as to produce knowledge of anything, to anything that cannot somehow be sensed. The application of concepts beyond the range of objects of possible sensory experiences, he held, yields no knowledge. Since God is not a candidate for being literally sensed, the concept 'God' can have no knowledge-providing application. Otto, working in Kant's shadow, proposed to substitute 'numinous ideograms' for concepts. God is inaccessible to reason, but, Otto held, can be felt in numinous experience, where one is encountered by God. This enables one to form an ideogram of God. Otto's examples of ideograms are 'the Void' and 'the Wholly Other', and he wrote that the necessity for ideogramic expression and the ineffability of the numinous experience 'teaches us the independence of the positive content of the experience from the implications of its overt positive expression' ([1917] 1923: 34). His acceptance of a Kantian perspective, his contention that numinous experience is incapable of full conceptualization, his view that God has a conceptually accessible aspect and a conceptually inaccessible aspect, and his attraction to negative theology blended together to yield talk about ideograms. None of this led Otto to conceive of God as irrational or to say that contradictions can be true of God. None the less, the force of 'ideogram' is suspiciously like that of 'concept', applied to something that is not an object of possible sense experience.

Otto is most famous for his emphasis on numinous experience, which ranges from a vague sense of the uncanny to explicit putative experiences of God. These latter, stronger versions of numinous experience form our primary grounds for thinking that there is a God. They are, Otto believed, genuine encounters with God, the powerful content of which leaves no doubt as to the reality of the experience's object. To have a numinous experience is to experience (at least apparently) a being who is majestic, awesome, living, holy and overwhelming, in whose presence one realizes one's unholiness, dependence and comparative insignificance. What is most important for Otto is the being that is experienced; one's reactions to it are but corollaries to the being's own attributes. Further, the object of numinous experience possesses ultimate and unsurpassable worth. A human being is passive, not active, in such experiences. Otto believed that such experiences guarantee their own veridicality, needing no help from natural theology or philosophical argument.

Kant claimed that moral experience is not reducible to any other sort of experience, and that morality has an indefeasible validity all its own. Otto agreed about morality and made the same claim regarding religion and

numinous experience. Thus he stressed that numinous experiences, while in some ways resembling other experiences, are none the less unique in their content. Further, they are inexplicable in natural terms. Hence religion has a genuine object and theology a distinct subject matter (see Religious experience).

However, it is not clear that even if numinous experience is indeed unique in kind that this yields veridicality; on one popular view of secondary qualities, each is unique in type and secondary qualities are mind-dependent. Nor is it clear that numinous experience is not veridical even if it is not unique in content. But be that as it may, Otto's emphasis on the centrality of numinous experience in monotheistic traditions has had a strong influence on the philosophy and phenomenology of religion.

Overton, Richard (d. *circa* 1665)

Overton was one of the leading figures of the radical Leveller movement in England in the 1640s. He fought for the equality of all men before the law and for complete religious and political toleration, often by appealing to notions such as the social contract and the natural law. In metaphysics he denied that the soul is a separate immaterial and immortal substance, arguing that immortality is not achieved until the resurrection. His views on the soul may have influenced Milton.

Overton's dates are unknown. An Englishman, he may have spent some time in the Netherlands and appears to have matriculated in Queens' College, Cambridge in 1631. He was most active from the early 1640s to the mid-1650s, and was arrested and imprisoned several times for political reasons. He probably died in the mid-1660s.

In numerous pamphlets, some of which were published under the pseudonym 'Martin Marpriest', Overton expressed his political views about religious toleration, democratic republicanism, the importance and dignity of the individual's property, and the equality of all men before the law. Often this was done in a vivid humorous and satirical style. While Overton appealed to notions such as the social contract and the natural law, he did not present any detailed philosophical analysis of these concepts. His most important pamphlets include: *The Araignement of Mr. Persecution* (1645) which contains his ideas on toleration; *A Remonstrance of Many Thousand Citizens* (1646a) which calls for the abandonment of monarchy, arguing that all power rests with the people; *An Arrow against all Tyrants* (1646b) which emphasizes the political rights of the individual; and *An Appeale from the Degenerate Representative Body of the Commons of England Assembled at Westminster* (1647) which upholds the principles of 'right reason' that in some circumstances justify a direct appeal to the people. Also important are his editorials for the weekly newspaper *The Moderate* (1648-9). It has been argued that Overton played an important role in the development of seventeenth-century 'possessive individualism' according to which the individual is naturally the owner of their own person. However, the nature of Overton's individualism is still a matter of dispute among scholars.

Overton's most philosophical work is *Mans Mortalitie* (1643) (a revised version of the book first appeared in 1655 under the title *Man wholly Mortal*). Overton's denial of an immaterial and immortal soul, and his view that all hope for a future life is in the resurrection, link his work to doctrines in early Christian thought. Some of Overton's arguments are similar to those of Pomponazzi in *On the Immortality of the Soul* (1516). Other influences include Socinianism, George Wither's introduction and translation of Nemesis' *The Nature of Man* (1636), and Henry Woolnor's *The True Originall of the Soule* (1642) (see Socinianism).

According to Overton, the belief in an immortal soul is a 'heathenish invention' which later made its way into Christian dogma. He attempts to argue for his position both through an interpretation of the Bible and through philosophical reasoning. His arguments are very much couched in scholastic terminology, for example, 'form and matter' and 'potentiality and actuality'. To a large extent, his strategy consists in pointing out absurdities in the immortalist position.

Overton's main philosophical argument against the natural immortality of the soul is based on his view that what is called 'the soul' is not an immaterial substance: since man is wholly a compound material being, he cannot be intrinsically indestructable or immortal. As in his political writings, Overton in *Mans Mortalitie* emphasizes the rationality of man, but for him, rationality does not entail immateriality. Rather, he argues that rationality is a function of man's material being. The difference between man and beast is said to be only a matter of degree. Man is an animal whose (physical) parts are endowed with several faculties which make him a 'living Rationall Creature'. All of man's faculties depend on the body and are thus mortal: this is true of faculties which men have in common with beasts as well as of those which are distinctive of man (that is, reason, consideration, science and so on). The faculties exist in the human body as accidents exist in a subject. It is only through the body that the faculties constitute a unitary human self; their 'unite substance' is in the body. If it were possible for man's faculties to exist independently of the body, we would have to assume as many souls as there are faculties. Thus we would be led to the absurd conclusion that each faculty constitutes a separate soul and that there is no unitary self to which the various faculties belong.

Overton infers from the essential physical nature of man that (1) man is not by nature indestructible or immortal and that (2) man's immortality is a gift of God received at the resurrection. Thus, Overton does not deny immortality altogether, but he makes the afterlife dependent on the resurrection. While he rejects the notion of an immaterial human soul, it is not clear that his 'materialism' extends universally. What he says about the soul is at least consistent with the view that there are non-human immaterial spirits (for example, angels). But he assigns to God a material dwelling-place in subscribing to the belief that the sun is the seat of divinity.

Mans Mortalitie aroused considerable controversy. It was attacked as heretical in the House of Commons in 1644, and it came under attack in print by Guy Holland in *The Prerogative of Man* (1645), Alexander Ross in *The Philosophicall Touchstone* (1645), Thomas Edwards in *Gangraena* (1646), and several others. On the positive side, Overton's views on the soul are sometimes said to have influenced Milton; but the matter is controversial.

Owen, Gwilym Ellis Lane (1922-82)

G.E.L. Owen led the reorientation in ancient philosophy that began in the 1950s in Britain and North America. He approached the texts with a profound knowledge of classical scholarship, but also as an analytic philosopher, understanding them as conceptual investigations of live philosophical interest. Concerned primarily with the logic of argumentation, philosophy of science and metaphysics, he wrote influential articles on Parmenides, Plato and Aristotle. Equally important were his classes at Oxford (1953-66), at Harvard (1966-73) and finally at Cambridge, in which he constantly developed and tested his ideas and methods.

1 Logic and metaphysics in Plato and Parmenides

After an interruption for war service, G.E.L. Owen completed his BA at Corpus Christi College, Oxford, and stayed on for the new graduate degree of B.Phil., which he took in 1950, the second year it was awarded. His B.Phil. thesis, written under the supervision of Gilbert Ryle, was a bold and far-reaching study of logic and metaphysics in the 'later dialogues' (as under his influence these particular works came to be called) of Plato: *Parmenides*, *Theaetetus*, *Sophist*, *Statesman* and *Philebus*; in it he laid the groundwork for the series of remarkable graduate seminars on Plato that he later gave at Oxford, Harvard and Cambridge. It led to his first article, 'The Place of the *Timaeus* in Plato's Dialogues' (1953), in which he set himself the task of overturning the scholarly consensus in regarding the *Timaeus* as the culmination of Plato's work in metaphysics. Timaeus majestically portrays the construction of the physical world by a god looking to separated Platonic Forms as models ('paradigms') of the qualities and substances to be imposed upon the transient 'flux' of physical reality. This seemed to Owen to rest on metaphysical theses, familiar from such 'middle-period' dialogues as *Phaedo* and *Republic*, that the more sophisticated 'later' dialogues had overthrown. So it was rather in the logical explorations of the 'later' dialogues that the high point of Platonic metaphysics was reached. In Owen's view, philosophically well-motivated ambitions had led Plato in the middle dialogues to linguistic and conceptual abuses in postulating the 'being', 'unity' and 'stability' of Forms and describing the character of physical objects as multiplicities that 'become' or 'appear' but 'are' not anything. Disturbed by the resulting logical difficulties and paradoxes, he undertook in the 'later' dialogues a careful examination of the logic of these and related concepts. He discovered that kind of philosophical analysis to be inherently rewarding, and hoped thereby to replace the earlier theory of Forms with a conceptually more adequate version. This early work of Owen's was carried forward later in brilliant papers on the analysis of being and not-being in the *Sophist* and on the antinomies about unity developed at length in the *Parmenides*. His work on the logical and metaphysical analyses of the 'later' dialogues fundamentally altered, and deepened, the study of these works - even if his arguments did not win most scholars over to dating the *Timaeus* early, close to the *Republic*.

Owen was the first University Lecturer at Oxford, and subsequently the first Professor, appointed specifically for Ancient Philosophy (1953); later he went to Harvard to establish a graduate programme there in Classics and Philosophy. He did massive research for his year-long lecture-courses at Oxford, attended also by graduate students, on the Presocratics. Only his interpretations of Parmenides and Zeno of elea were ever published. For Owen, Parmenides was a 'philosophical pioneer of the first water', not the cosmologist in the tradition of Anaximander that conventional scholarship saw. He stood self-consciously aside from that tradition, using independent deductions to work out the characteristics that, by force of logic, reality must possess. He argued that anything that can be thought of or spoken about must 'be' or 'exist', and that what 'is not' or 'does not exist' is literally unthinkable. Since change, differentiation and plurality of any kind would logically require the being of what 'is not', reality must be a single, timeless, spatially continuous, internally undifferentiated, unchanging entity. Reality as it appears to us, and as the earlier cosmologists represented it, is essentially diverse and changing. But Parmenides' 'much-contested proof' reveals how seductive conventions of human thought are which, despite their logical appearance, rest on logically unacceptable foundations.

2 Dialectic, physics and metaphysics in Aristotle

More than half of Owen's published papers, and a similar proportion of his teaching, dealt with Aristotle. Here again, he was primarily interested in the logic of arguments. In a reversal of Werner Jaeger's then-dominant picture of Aristotle's philosophical development, Owen showed that Aristotle's early work in logic had led him

while still a member of Plato’s Academy to reject Plato’s theory of Forms. Only much later did independent study lead to a sort of ‘Platonism’ in his metaphysical thought. Central to Owen’s work on Aristotle was his account of the role of ‘dialectic’, presented in ‘*Tithenai ta phainomena*’ (1961): this title refers to the process of ‘setting down’ the phenomena needing to be sorted out in order to reach a general theory in some area of inquiry. As Owen noticed, even in a subject like physics the ‘phenomena’ for Aristotle are mostly not results of observation, but certain opinions *about* what is observed: matters of common or customary opinion, or ordinary linguistic usage, or the views of the ‘wise’ - respected philosophers or other experts. A ‘dialectical’ inquiry works through these ‘phenomena’ so as to discover and then resolve tensions among them by making appropriate distinctions: the ‘true’ theory is the one that can claim maximum support from the phenomena once so reconstructed. For Owen, such ‘dialectical’ reasoning was a paradigm of good philosophical method. He examined it in several contexts in Aristotle’s *Physics*, especially the theories of time and motion, and at several stages of Aristotle’s engagement with ‘first philosophy’, or metaphysics.

Owen’s students, and others who came under his influence in formative years, spearheaded a wide expansion of work on ancient philosophy. Their research includes logic, metaphysics and philosophy of science, but also ethics, political philosophy, philosophy of mind and other fields, and it extends into the post-Classical periods of Hellenistic, Roman and later ancient philosophy.

Oxford Calculators

'Oxford Calculators' is a modern label for a group of thinkers at Oxford in the mid-fourteenth century, whose approach to problems was noticed in the immediately succeeding centuries because of their tendency to solve by 'calculations' all sorts of problems previously addressed by other methods. If for example the question was, what must a monk do to obey the precept of his abbot to pray night and day, a 'calculator' might immediately rephrase the question to ask whether there is a minimum time spent in prayer that would be sufficient to fulfil the abbot's precept, or a maximum time spent that would be insufficient to fulfil the precept. Or, if grace was supposed to be both what enables a Christian to act meritoriously and a reward for having so acted, then a calculator might ask whether the degree of grace correlated with a meritorious act occurs at the moment of the meritorious act, before the act when the decision to act is being made, or after the act when the reward of increased grace is given. If a body was hot at one end but cold at the other, then a calculator might ask not whether it is to be labelled hot or cold, but how *hot it is as a whole. Finally, if it was asked whether a heavy body acts as a whole or as the sum of its parts, then a calculator might take the case of a long thin rod falling through a tunnel pierced through the centre of the earth and attempt to calculate how the rod's velocity would decrease as parts of the rod passed the center of the cosmos, if it acted as the sum of its parts.*

*Of these four questions, the last two were asked by Richard Swineshead, a mid-fourteenth century fellow of Merton College, Oxford, whose Liber calculationum (Book of Calculations) led to his being given the name 'Calculator'. By association with Richard Swineshead, other Oxford masters including Thomas Bradwardine, Richard Kilvington, William Heytesbury, Roger Swineshead and John Dumbleton have been labelled the 'Oxford Calculators'. Their work contains a distinctive combination of logical and quantitative techniques, which results from the fact that it was often utilized in disputations on sophismata (*de sophismatibus*). This same group of thinkers, with emphasis on their mathematical rather than logical work, has been called the 'Merton School', because many but not all of the Calculators were associated with Merton College, Oxford. Besides calculatory works, the same authors wrote works in which calculatory techniques are not so prominent, including commentaries on Aristotle, mathematical compendia and commentaries on Peter Lombard's Sentences.*

1 Richard Swineshead's *Liber calculationum*

The central book of the Oxford calculatory tradition, the *Liber calculationum (Book of Calculations)* focuses on applications of mathematical techniques to natural philosophical problems (Murdoch and Sylla 1976). Of the sixteen treatises of the *Liber calculationum*, the first four deal with the intension and remission of forms or the increase and decrease of qualities such as heat or whiteness. First, the issue of the intension and remission of forms is raised in the abstract. Should the degree of heat, for instance, be measured by nearness to the maximum degree of heat or by the distance from zero degree (Clagett 1950)? Second, questions concerning the intension and remission of forms are raised concerning a body nonuniformly qualified with heat or some other quality. Should it be said to be as hot as its maximum degree or as hot as its mean degree? Third, how should one characterize the combined degree of an element having two unequal qualities, such as heat and moisture: is the combined degree as intense as the mean between its degree of heat and its degree of moisture or is it, for example, only as intense as the more remiss quality? Swineshead concludes that such an element is as intense as the geometric mean between its two qualities, so that if one quality is in the second degree and the other in the eighth, then the element as a whole should be said to be in the fourth degree.

Having debated and determined such questions about the measures of qualities, the *Liber calculationum* turns next to measurements of quantities of bodies, first to degrees of density or rarity and then to measures of velocity of augmentation and diminution. Treatise VII deals with the problem of reaction. If a hot body heats the cold body next to it, will the cold body simultaneously react and cool the hot body? If, for action to occur, the agent must have more power than what it acts on, how can each of the two neighbouring bodies have sufficient power to act on the other at the same time? Treatise VIII consequently asks directly how the power of an agent should be measured. Is it, for instance, by its intensity, so that a body hot in the fourth degree would have a power in the fourth degree? Or does power depend on the 'multitude of form', taken to depend not only upon the intensity and extension of the form, but also upon the density of the matter in which it inheres? Also, how is the 'difficulty of action' to be measured? Is it by the ratio between the power of the agent and the resistance or is it, as Swineshead

concludes, simply by the power of the agent acting to its utmost?

Treatise X deals with maxima and minima and Treatise XI with the problem, mentioned at the start of this article, of a thin rod moving through the centre of the earth (Hoskin and Molland 1966). Treatises XII and XIII deal with illumination and the action of light sources. Treatises XIV and XV deal with problems of quantifying local motion with respect to its causes, first explaining in the abstract how velocity varies when the ratio of force to resistance varies, assuming the truth of Thomas Bradwardine's dynamical function (see Bradwardine, T.), and second in the concrete, assuming that resistance is encountered by an agent as it moves through a medium of varying resistance. Finally, Treatise XVI of the *Liber calculationum* deals with the rates at which a body takes on the maximum degree of a quality; as, for instance, a heating agent warms a body next to it, first assimilating the parts of the body nearest to the agent and then parts farther away.

As can be seen from this brief survey of the contents of the *Liber calculationum*, the Oxford 'calculations' in their core manifestation concerned every technique that had been developed up to that time for introducing quantification into natural philosophy, plus some new ones (see Natural philosophy, medieval). The intension and remission of forms was a type of quantification previously most highly developed in determining the degrees of compound medicines. Measurements of illumination had been developed within the science of optics or perspective and possibly also in astrology, where each planet was supposed to exert an influence on earth depending upon its position in the heavens. Ways of relating forces, resistances and velocities of local motion had received a thorough treatment in Thomas Bradwardine's *De proportionibus velocitatum in motibus (On the Ratios of Velocities in Motion)*, completed in 1328. The 'calculator' focused his attention only on physical questions, but the theory of intension and remission of forms had been and continued to be applied by others to the intension and remission of charity or grace in the human soul, and calculations could also be applied in theology.

2 Calculations and disputations on sophismata

What gave 'calculations' their distinctive style was the fact that they were connected not only to natural philosophy or theology, but also to the disputations on sophismata (*de sophismatibus*) prominent at Oxford in this period (Sylla 1982). As exercises occurring at the culmination of the undergraduate curriculum, disputations on sophismata were devoted to the explication of propositions that are at first glance counterintuitive, such as 'Infinite are finite' (*Infinita sunt finita*) or 'Socrates is whiter than Plato begins to be white'. In an oral disputation on a sophisma, students or masters competed against each other in proposing and arguing for and against possible resolutions. In an earlier period, disputations *de sophismatibus* called upon the disputants to use especially what they knew of logical or grammatical theory. As time went on, natural philosophy and mathematics were also called upon, thus resulting in the so-called calculations.

What disputations *de sophismatibus* were like in earlier fourteenth-century Oxford, before calculations became prominent, can be seen in Richard Kilvington's *Sophismata*, which includes the sophisma mentioned above, 'Socrates is whiter than Plato begins to be white' (Kretzmann and Kretzmann 1990) (see Kilvington, R.). Assuming the case that Socrates has some degree of whiteness and that Plato begins to intensify in whiteness starting from zero, the sophisma sentence seems to apply, but not without problems. Suppose that the comparative term 'whiter' is taken to be measured by the ratio of the more intense quality to the less intense, so that if Socrates is white in the second degree and Plato in the first degree, then Socrates will be said to be twice as white as Plato. If Plato has zero whiteness at t0 and subsequently begins to intensify in whiteness, then when one considers the ratio between the whiteness of Socrates and that of Plato, it will get larger towards the beginning of Plato's intensification, tending to infinity as Plato's whiteness tends to zero. It seems to follow that immediately after Plato begins to intensify in whiteness, Socrates will be infinitely whiter than Plato, but this seems to be contradictory, it might be argued, because Socrates is only finitely white. Is something wrong with the analysis? Confronted with such sophismata, Oxford scholars concluded that it might be useful to study systematically how any and all things should be quantified.

William Heytesbury's *Sophismata* and *Regulae solvendi sophismata (Rules for Solving Sophismata)* exemplify the forms that Oxford disputations on sophismata took after the introduction of calculations (Wilson 1956). Heytesbury divides his rules for solving sophismata according to set techniques, referred to by historians as 'analytical languages' or 'conceptual algorithms' (Murdoch 1969, 1975). There are purely logical techniques, such as ways of solving 'insolubilia', or self-falsifying propositions, such as 'I am telling a lie'. Other techniques

analyze sophismata in terms of first and last instants, maxima and minima, and measures of motion in the categories of local motion, alteration, and augmentation and diminution. The same sophisma sentence could be analysed on different occasions applied to different hypothetical situations (‘cases’) and using different analytical languages. Thus the sophisma sentence ‘Socrates is whiter than Plato begins to be white’ might be analysed by considering that motion of alteration is a so-called successive entity extrinsically limited at its beginning and its end; there is no first instant of alteration but only a last instant before the alteration begins, and no last instant of alteration but only the first instant at which the final degree has been induced.

On another occasion the same sophisma sentence could be analyzed using the language of maxima and minima, pointing out that as Plato moves from zero whiteness the intension of whiteness increases continuously, so that there is no minimum degree of whiteness gained, but rather smaller and smaller degrees *ad infinitum* down to zero. When the implication was drawn from the case that if relative intensities are measured by the ratio they have to each other, then Socrates will be infinitely whiter than Plato immediately after he begins to be white, then the sophisma sentence could be analyzed using distinctions about senses of the words ‘immediate’ and ‘infinite’. Sometimes ‘infinite’ is used to mean a ‘potential infinite’, and sometimes an ‘actual infinite’. Thus the integers are potentially infinite because, given any integer, one can find a higher integer; but the integers are not actually infinite because there is no single infinite number. Heytesbury’s *Sophismata* demonstrates in practice the many rules that he lays out in the *Regulae solvendi sophismata*.

3 Calculations and measures of motion

The Oxford Calculators’ belief in the potential power of mathematics to solve problems of sophismata seems to have been inspired by the success of Thomas Bradwardine’s *De proportionibus velocitatum in motibus* (Crosby 1955) (see Bradwardine, T.). Bradwardine had shown how neatly the Euclidian theory of ratios could be used to clarify the relations of forces, resistances and velocities in motions as discussed with less success in Aristotle’s *Physics*. Bradwardine’s function, relating forces, resistances and velocities, was said to measure motion with respect to its cause (*tanquam penes causam*), while measures of the distances traversed or intensities or sizes gained were said to be measures with respect to effect (*tanquam penes effectum*). Discussions of alternative ways of measuring local motion, alteration, and augmentation and diminution *tanquam penes effectum* are common in the works of the Oxford Calculators.

4 Calculations and logic

These mathematical considerations were introduced into a context that had already been highly developed through the application of the new logic, especially the theories of supposition and syncategoremata (see Language, medieval theories of; Logic, medieval). The problematic meaning of a sophisma could be shown to result from a confusion of compounded and divided senses, as in the sentence ‘Something white can be black’. The word ‘infinite’ was said to have a syncategorematic sense, corresponding to the potential infinite, as well as a categorematic sense, corresponding to the actual infinite. The sophisma sentence ‘Infinite are finite’ was explained by saying that when ‘infinite’ appears at the beginning of a sentence, it is to be taken syncategorematically. There is not one thing that is infinite, but many things which together are infinite. In this way the calculators could conclude that there is no one infinite number, but all the numbers together are infinite, meaning something like the modern statement that the set of all integers is infinite.

5 *De incipit et desinit*; maxima and minima

Walter Burley, in his work on first and last instants and in his works on intension and remission of forms, had developed techniques that were also used as analytical languages by the later Calculators. As described above, the technique of first and last instants or of analyzing the use of the verbs ‘it begins’ and ‘it ceases’ (*incipit et desinit*), distinguished whether a permanent form (such as whiteness) or a successive entity (such as the motion of traversing a distance) has a first instant of being or a last instant of non-being. Using the analytical language of maxima and minima, it might be asked whether there is a maximum weight that Socrates can carry or a minimum weight too heavy for him. Again, propositions or sophismata would be analyzed using supposition theory to see which alternative was the correct one.

6 Calculations and natural philosophy

After their development, the techniques of the Oxford Calculators were also applied not only to solving explicitly labelled sophismata, but also to dealing with the normal questions of natural philosophy (see Natural philosophy, medieval). Roger Swineshead, author of the *Obligationes* and *Insolubilia* (and thought to be a distinct person from Richard Swineshead, despite a confusion of names in the manuscripts), made such an application in his *De motibus naturalibus (On Natural Motions)*, alternating sections dealing with motion in the categories of place, quality and quantity with sections explicitly devoted to measures of motion, often proposing sophismata that could be developed using these measures. Thus Roger Swineshead proposed that a body which gains a degree uniformly throughout is altered indivisibly more than a body which in the end is non-uniformly qualified with the given degree as the minimum uniform degree that does not qualify it.

Calculatory techniques were also used by John Dumbleton, author of a large *Summa logicae et philosophiae naturalis (Summa of Logic and Natural Philosophy)* which combined calculation with something resembling a commentary on the natural works of Aristotle. Thus the techniques of the Oxford Calculators were seen as useful in the ordinary business of natural philosophy, although they gained their special flavor by frequent use in disputations *de sophismatibus*.

7 Calculations and theology

Shortly after they were put to use in the disputations *de sophismatibus*, the techniques of the Oxford Calculators became very popular at Paris and elsewhere, often in combination with the nominalistic analyses associated with William of Ockham. Bachelors of theology commenting on Peter Lombard's *Sentences* frequently used calculatory techniques to address theological problems. In many cases, calculatory techniques indeed helped to resolve technical questions such as those concerned with degrees of grace or with first and last instants (for example, whether there is a first instant of salvation or a last instant of sinfulness). While some commentators applied the calculatory techniques wherever possible, others deplored the invasion of such quibbling technicalities into sacred subjects (Murdoch 1978).

Paine, Thomas (1737-1809)

Thomas Paine, born in Norfolk, England, spent his early years as an undistinguished artisan and later excise officer. In 1774 he emigrated to America and settled in Philadelphia where he became a journalist and essayist. His Common Sense (1776) and sixteen essays on The Crisis (1776-83) were stunning examples of political propaganda and theorizing. In the late 1780s, in Europe, Paine wrote The Rights of Man (1791-2) and attacked the English political system. During the French Revolution he was a Girondin in the French Convention and wrote The Age of Reason (1794, 1796), savagely criticizing Christianity. He died in New York in 1809, an important figure in the sweep of the revolutionary politics in America, England, and France at the end of the eighteenth century.

1 Background and republican political theorizing

Thomas Paine was born on 29 January 1737 in Thetford, in Norfolk, England, where he spent the first thirty-seven years of his life, a poor, unsuccessful, and unknown artisan. In desperation he emigrated to America in 1774 and rapidly received recognition as an intellectual leader of the American Revolution.

The juxtaposition of Paine's early career and later fame has attracted wide attention. In periods of conservative stability Paine has been reviled as an extreme radical on the fringes of the American Revolution, a demagogic drunkard not fit to be associated with the Founding Fathers of the United States. In periods of ferment commentators have hailed Paine as an authentic democrat of the people, whose thought and practice can be a model for the left.

Paine's natural talents and the more open social structure of America obviously contributed to the astonishing improvement in his fortunes by the mid-1770s. But the colonial uprising was mainly middle-class in its orientation, led by the political gentry. In this social milieu Paine was something of an outsider. His background and personality made him unpredictable and never fully acceptable. He himself was never at ease in the upper reaches of the society he was helping to create, although he gloried in the recognition and status he had achieved.

Paine's success was to some extent a product of his marginal status. He had a shrewd understanding of the actual political world and was zealously committed to government by and for the masses. But he was no more an erudite thinker than the other American founders, nor were his political notions unconventional in their context. None the less, he had the rare gift - always presumed to be the produce of his working life - of being able to write for the populace. Paine understood what the people wanted or needed to hear better than any of the other Founding Fathers. All of his tracts from the seventies to the nineties hit the nerve of popular debate while simultaneously advancing the democratic ideas that the Americans had taken from John Locke and the English 'Commonwealthmen'.

Paine was interested in applied science and absorbed popular expressions of Newtonian physics (see Newton, I.). A series of laws governed the natural world. They were open to the understanding of all and could be put to work for human benefit. Paine was a 'rationalist' in an era termed the American Enlightenment, believing that fundamental truths could be arrived at by careful investigation and reflection on experience. Thus, he rejected Christianity, as depending on unreasonable beliefs (for example, the Virgin birth), and delighted in pointing out inconsistencies in the Bible. Instead, the harmonies of the natural world led one to conclude that a benevolent Deity had created an ordered cosmos. This 'clockwork' God did not, however, intervene directly in human life but had imprinted humankind with moral impulses that enabled people to achieve happiness on earth once they had rationally considered their own best interests.

This set of metaphysical and moral beliefs led to a grasp of political life that was indebted to Locke and crucial to Paine's philosophical politics. The creator allocated 'natural rights' to all people - or at least all men - equally. Differences in station were justified only because of variations in talent, industry, and frugality. In the order of things men should be provided with equal opportunities and an equal voice in determining how society should be governed. Society was the natural outcome of the human condition - the relationships that derived from human beings living together, raising their young, and co-operating in common endeavour. These joint implicit responsibilities embodied the social contract. On the other side, government was a negative instrument only

necessary to the extent that matters went awry; its powers were limited and, in the natural course of things, largely unnecessary.

What had gone wrong in America to impel the nation's leaders to revolution? Paine and others like him embraced the views of some dissenters in England earlier in the eighteenth century. These Commonwealthmen had developed a critique of English society that supposed the monetary power of the Crown to have destroyed balanced government. The Commonwealthmen looked back to a time of imagined civic virtue and forward to a restoration of the natural scheme of governance.

At the end of the eighteenth century, Paine popularized and extended this view in America, leavening it with Lockean individualism. This was the 'republicanism' of the colonies, which combined a constellation of historical, political, and philosophical ideas. The opponents of the Commonwealthmen, Paine said, had triumphed in England, corrupted its society, and wished to place a yoke of tyranny on the colonies. Paine, in contrast, urged the liberty of individual conscience, religious toleration, resistance to tyrants, and reform of the legislature. He denounced hereditary political institutions and desired to lodge power with 'the people', no matter how restrictedly they were defined.

2 Propaganda against England

Paine elaborated these views in the 1770s as the most inflammatory and didactic exhorter of the Revolutionary forces. *Common Sense* (1776) presented a justification for the Revolution, and the first *Crisis* paper (1776) is sometimes credited with keeping the Revolutionary army intact during the early fighting. In the 1780s Paine joined the Federalists in supporting a new constitution. He believed that a powerful central authority would promote the commercial and territorial expansion he desired, and he saw the Federalists as safeguarding *laissez-faire* economics in a democratic empire.

When Paine returned to Europe in the late 1780s, however, he focused again on theorizing about revolution, especially the one occurring in France and its potential for human liberation. At the same time he hoped to change the contours of English politics. Although first welcomed by men like Edmund Burke, who had sympathized with the American colonies, Paine became disgusted with the possibilities for renewal of the English system. *The Rights of Man* (1791-2) explicitly attacked Burke's ideas and defended the French Revolution. Paine was contemptuous of the claims of tradition and custom that led to commitment to a hereditary monarchy. The book's praise of French politics also signalled a break with the increasingly conservative American Federalists who came to fear the radicalism of the Continent.

The Rights of Man additionally suggested ways in which a republic could effect the rudiments of a welfare state, and hinted at the potential for redistributive economic justice. This concern was later fleshed out in *Agrarian Justice* (1797). But even in 1792 Paine had gone too far for English authorities and was indicted for sedition. He fled to Paris in September. The events of the 1790s and his writings in that decade have ever after made him a hero to the English left.

3 Role in the French Revolution

In France Paine combined the political theorizing and revolutionary action that were characteristic of his career. But when the Girondins lost control of the Convention and the French Terror began, Paine was endangered. Isolated by his ignorance of the language, he refused to alter his now conservative ideas and was taken to the prison where he assumed he would be put to death. In 1794, however, he was released and lived quietly with the American Ambassador to France, James Monroe.

In *The Age of Reason* (1794), written during this time in France, Paine returned to his religious concerns. He articulated the premises of Enlightenment Deism (see Deism) but also bitterly assaulted Christianity and its biblical basis. Too conservative in France, his religious views proved too hostile to established institutions when he returned to America in 1802. He was vilified in many quarters as a representative of the Anti-Christ and lived out his last years in penury and public disgrace.

Paley, William (1743-1805)

William Paley, theologian and moral philosopher, expressed and codified the views and arguments of orthodox Christianity and the conservative moral and political thought of eighteenth-century England. Paley says that his works form a unified system based on natural religion. Like others during this period, Paley thought that reason alone, unaided by revelation, would establish many Christian theses. He is confident that a scientific understanding of nature will support the claim that God is the author of nature. Paley belongs to the anti-deist tradition that holds that revelation supplements natural religion. The most important revelation is God's assurance of an afterlife in which the virtuous are rewarded and the vicious are punished. Natural and revealed religion, in turn, provide the foundation for morality. God's will determines what is right and his power to reward and punish us in the afterlife provide the moral sanctions. On the whole, Paley is concerned with sustaining Christian faith, and ensuring that people known what their duties are and do them.

1 Life and writings

Paley was born in Peterborough, England. He entered Christ's College Cambridge in 1759 and graduated in 1763 with highest distinction. After teaching for a few years in a small school, he returned to Cambridge where he taught moral philosophy, divinity and Greek testament for nine years. His lectures were noted for their clarity and lucid organization. He left Cambridge when he married, obtaining the first of various positions in the Church of England, the highest as archdeacon of Carlisle.

Paley wrote four books. In the first, *The Principles of Moral and Political Philosophy* (1785), he defends theological utilitarianism. In his *Horae Paulinae: Or The Truth of the Scripture History of St Paul Evinced* (1790), he defends the authenticity of the New Testament writings, in particular the scriptural history of St Paul. In *A View of the Evidences of Christianity* (1794), he defends revelation and argues for the veracity of Christian miracles. In *Natural Theology* (1802), his best known work today, Paley develops a detailed statement of the argument from design. Except for his *Horae Pauline*, his writings enjoyed a huge success and went through numerous reprintings. His *Principles* was adopted as a textbook at Cambridge in 1786 and his *Evidences* in 1822, and both were used as textbooks in England and the United States until well into the mid-1800s. His portrait hangs in Christ's College along with those of Milton and Darwin. His works, however, have by and large faded into obscurity.

2 Theological and apologetical writings

Paley addresses his *Natural Theology* to Christian readers with the hope that it may help to sustain their belief in God in times of doubt and that they may come to see the world as a 'temple' and life as 'an act of adoration'. The argument of the *Natural Theology* has two parts. In both parts he defends the argument from design against some traditional objections (see God, arguments for the existence of). First, Paley wants to establish that there are strong rational grounds for belief in the existence of God. He argues that the natural order, like a watch, was clearly designed for a purpose. As in the case of the watch, we should infer that the universe had an intelligent creator. Because each example alone is sufficient to support the conclusion that there is an intelligent author of nature, Paley says that by enumerating examples he is adding to the proof. He offers many detailed examples to support the claim that the various parts of nature are like machines exhibiting design and purpose. Most of his examples are from anatomy, and his favourite is the eye. Its intricate structure parallels that of a telescope and both obviously serve a purpose. Paley considers but dismisses a number of alternative explanations for the purposefulness of the natural world. For example, he argues that nature's intricate structure is so striking that it could not be a product of the chance coming together of atoms.

Second, Paley argues that a scientific understanding of nature helps to establish the traditional attributes of a Christian God. God is a person, since, as a contriver, he must have a mind. The fact that nature exhibits a uniform plan suggests his unity, although Paley acknowledges that this only shows a 'unity of counsel'. As cause of nature, God's power and intelligence must be adequate to their effect, yet the terms 'omniscient' and 'omnipotent', he admits, are only convenient superlatives. Paley devotes considerable effort to attempting to establish God's benevolence, arguing that the contrivances of nature are beneficial and that it is 'a happy world after all'. In addition, God gave us and other animals the capacity to experience pleasure, even though, he assumed, pleasure is biologically unnecessary. But Paley concedes that natural religion cannot by itself solve the problem of evil (see

Evil, problem of).

Paley addresses the credibility of christian revelation in his *Evidences*. He assumes that God chose to reveal his will to the early Christians by performing miracles. The credibility of revelation thus turns on whether there are good reasons for believing that these miracles occurred. But David Hume (1777) had argued that it is contrary to experience that miracles should be true, but consistent with experience that testimony should be false (see Hume, D. §2; Miracles). So there are two issues: should we believe in the occurrence of miracles, and is the testimony of the witnesses credible? Paley takes up these issues one by one. What tells against miracles, Hume thought, is the fact that the laws of nature work uniformly. Paley counters that if we have independent proof that there is a God who created the universe - including the laws of nature - for special purposes, it is not improbable that God may have occasionally intervened in the natural order. In response to Hume's charge that the witnesses to miracles are not credible, Paley replies that the suffering of the early converts demonstrates their sincerity. Both Christian and non-Christian sources attest to their ordeals. Moreover, the New Testament writings are authentic, neither forged nor altered during their transmission. Further support for their authenticity is given in *Horae Paulinae*. The many undesigned coincidences between the Acts of the Apostles and Paul's letters, Paley argues, show that neither is fraudulent. In the *Evidences* Paley also responds to Hume's complaint that the miracle stories of various religions undermine each other's credibility, arguing that those of other religions may be dismissed on a number of grounds, including delusion and exaggeration.

3 Ethical and political writings

Paley insists that natural and revealed religion are the true foundation for morality, chastising those moralists who decline to bring in scriptural authorities. He also complains that most earlier theorists did not pay sufficient attention to working out what in specific instances our duties are, and getting people to do them. The key elements of Paley's theory are summed up in his three-part definition of virtue: 'the doing of good to mankind, in obedience to the will of God, and for the sake of everlasting happiness' (1785: 47). Paley is a theological voluntarist: God's will ultimately determines what is right (see Voluntarism). Since God is benevolent and wills our happiness, the rule we should use in deciding what to do is the utility principle. Right actions are those which promote the general happiness. Although we are basically self-interested creatures, God's power to reward and punish us in an afterlife make it in our interest to promote the happiness of others. Paley thinks that moral obligation is an unproblematic notion. It is like the obligation of a soldier to obey his officer or a servant his master, namely, being 'urged by a violent motive resulting from the command of another' (1785: 66). As Paley acknowledges, the only difference between prudential and moral obligation on this view is that the sanctions attaching to prudence are confined to this world whereas moral sanctions look to the 'world to come' (1785: 71).

Most of the *Principles* consists in a detailed discussion of our duties to God, others and ourselves. The last section contains his political theory. In most cases Paley defends the status quo. He does not use the utility principle as a tool of reform as did the later utilitarians. He argues that it is consistent with God's will that people own property and that the positive law of each country should regulate its distribution. He also argues that inequalities in wealth are advantageous to society, increasing productivity, and hence the general happiness. Like other utilitarians, Paley objects to the social contract theory. He traces the origin of government to paternal authority and the need for strong leaders in times of war. Citizens continue to obey out of habit and self-interest. The reason people ought to obey government is that God wills the general happiness and civil society promotes that end. In his discussion of more topical issues, Paley, as might be expected, defends the status quo; even so, throughout his adult life he vehemently opposed the slave trade and actively sought to end it.

List of works

There is no modern edition of Paley's works, but his works are readily available in many libraries. Selections from his *Natural Theology* are to be found in numerous introductory philosophy textbooks and in anthologies of classical readings in philosophy of religion.

Paley, W. (1785) *The Principles of Moral and Political Philosophy*, Dublin: Exshaw, White.(Based on lectures Paley gave while teaching at Cambridge, its success is said to have moved Bentham to publish his *Introduction*

to the Principles of Morals and Legislation. The opening sections contain his objections to the moral sense theory and a defence of theological utilitarianism. The rest of the book consists in a detailed discussion of our particular duties to God, others and ourselves, as well as Paley's political theory.)

Paley, W. (1790) *Horae Paulinae: Or The Truth of the Scripture History of St Paul, Evinced by a Comparison of the Epistles which bear his Name with the Acts of the Apostles, and with one another*, London and Dublin.(This is a work in Christian apologetics and is the least philosophically interesting of Paley's writings. He defends the authenticity of both the Acts of the Apostles and Paul's thirteen letters.)

Paley, W. (1794) *A View of the Evidences of Christianity. In three parts*, London and Dublin.(A work in Christian apologetics, Paley defends the credibility of Christian miracles and so Christian revelation against Hume's objections. He thinks this task is important because revelation is our only assurance of an afterlife in which the good are rewarded and the evil are punished.)

Paley, W. (1802) *Natural Theology: Or, Evidences of the Existence and Attributes of the Deity, collected from the Appearances of Nature*, London: Faulder and Philadelphia, PA: John Morgan.(The most widely read of Paley's works, it contains a detailed restatement of the argument from design. Although Hume's *Dialogues on Natural Religion* (1779) consists in a sustained and devastating attack on the argument from design, Paley does not reply to these objections.)

Contains a slightly more comprehensive selection of the theoretically interesting parts of Paley's moral theory, including his objections to the moral sense theory and his account of rights.)

Panaetius (*c*.185-*c*.110 BC)

Panaetius, a Greek philosopher from Rhodes, brought new vitality to Stoicism in the second century BC by shifting the focus of its ethical theory from the idealized sage to the practical problems of ordinary people. Working a century after Chrysippus had systematized Stoicism, Panaetius is often labelled the founder of 'Middle Stoicism' for defending new and generally more moderate positions on several issues. Because none of his writings survive, his influence is hard to gauge precisely and easily underrated. But his impact, especially in Rome where he was closely associated with many in the ruling elite, was profound. His emphasis on public service and the obligations imposed by power and high station probably helped shape the ideology of Roman imperialism. Through Cicero, whose writings preserve many of his ideas, he had lasting influence, especially on early modern moral and political thought.

1 Life and works

Panaetius, the eldest son of an eminent family on the commercially important Greek island of Rhodes, studied at the great library in Pergamum before coming to Athens in the 150s BC. There he studied under Diogenes of Babylon, the leading Stoic of the time. Visiting Rome in the 140s BC, he stimulated intense interest in Greek philosophy in general and Stoicism in particular among the so-called 'Scipionic circle' - a loose-knit group of politically conservative but culturally philhellenic nobles centred on Scipio Aemilianus (then the dominant figure in Rome) and idealized in Cicero's dialogue *On the Republic*. He accompanied Scipio as an informal advisor on a major diplomatic tour of Egypt, Asia Minor and Greece in 140-138 BC, then returned to Athens. Around 130 BC he succeeded Antipater of Tarsus as head of the Stoic school in Athens and taught there until his death about twenty years later. The most notable of his numerous students was Posidonius.

Famously learned, Panaetius wrote on geography, astronomy, musical theory and philology as well as philosophical subjects. But none of his books survives, and while extant works by many other writers are indebted to his work, a shortage of explicit citations makes it impossible to reconstruct his thought in detail. We are best informed about his treatise *On Duty*, which Cicero (§2) followed closely in writing *On Duties* (see §2). Other works included *On Providence* (used by Cicero in *On the Nature of the Gods*), *On Equanimity* (a major source for essays on the same theme by Seneca and Plutarch), a work on enduring pain and another on government. Living at a time of renewed interest in earlier philosophy, Panaetius especially admired Aristotle (probably for his lost dialogues and not the extant treatises) and above all Plato, whom he styled 'the Homer of philosophers' and quoted often. He also discussed the life and thought of Socrates and his companions, and the authenticity of dialogues ascribed to Plato and others.

Panaetius arrived in Athens when the Stoic system elaborated by Chrysippus and his successors faced acute criticism from rival schools of philosophy, and, although his most original and influential work was in ethics, he proposed modifying Stoic positions in other areas as well. He joined Academic sceptics in marshalling arguments against the validity of divination, which earlier Stoics had considered a reliable science and an important sign of providence; against astrology, for example, he cited the remoteness of the stars, diversity in the lives and characters of twins, and the manifest influence of heredity and environment. In cosmology, he vigorously defended the Stoic conception of the cosmos as directed by an immanent providential deity but abandoned the two closely related doctrines of cosmic conflagrations and eternal recurrence (whereby the universe is periodically reduced to undifferentiated fire, then regenerated identically in an everlasting cycle) (see Stoicism §5) in favour of the Aristotelian thesis that the cosmos is everlasting. In philosophy of mind, he simplified the Stoic model of the soul by restricting it to cognitive and appetitive functions. He also argued that inherited psychic traits show that the human soul is mortal, on the ground that inheritance entails birth and anything born must die.

2 Practical ethics

Panaetius' most enduring legacy is in ethics, where he significantly broadened the appeal of Stoicism by formulating a theory of obligation rich in implications for all social ranks and especially for the conduct of public affairs. Although his writings are lost, much of his theory survives in Cicero's *On Duties*, which was closely modelled on his own treatise *On Duty*. There Panaetius focused on two questions: what actions does virtue require, and what actions are advantageous? (Cicero chides him for neglecting what to do when the two conflict, but then

justifies the omission by arguing that conflicts are illusory because transgressing virtue is never really advantageous.) Downplaying the gap between doing what is right and doing it from perfectly virtuous motives - encapsulated in the Stoic distinction between 'duties' or 'appropriate acts' (*kathēkonta*) and 'correct acts' (*katorthēmata*) (see Stoicism §§15-16) - Panaetius emphasized practical precepts over abstract principles, and, in order to help people of imperfect character make 'progress' toward virtue, he constructed systematic rules of conduct for the proper pursuit and use of things that Stoicism maintained have only instrumental value, such as wealth, power and prestige.

Panaetius based his proposals on the Stoic account of moral development through a natural process called 'familiarization' or 'affiliation' (*oikeiōsis*) (see Hierocles; Stoicism §14). But he refined this theory by tracing all four cardinal virtues back to infant roots: wisdom to an innate desire for knowledge, justice to the social impulses inherent in rationality, courage to an impetus to excel, and temperance to an instinct for self-preservation. Accordingly he reformulated the Stoic acount of the human good - originally defined as 'living virtuously' and standardly explicated as 'living in agreement with nature' - as 'living by our naturally given propensities'. This richer picture of human nature served in part to answer charges that the Stoic ideal of virtue was neither natural nor attainable: by ascribing 'seeds' of virtue to everyone, Panaetius highlighted the continuity between normal human tendencies and the perfect virtue of a sage. But his account also justified assigning greater moral worth to ordinary people and their actions; and in his treatment of the several virtues he paid little attention to how a sage would behave and a great deal to what everyone else should do.

In charting the duties associated with each virtue, Panaetius gave new prominence to positive obligations involving the wellbeing of society and its members. Justice, for instance, he extended to include not only prohibitions against causing harm to others but also duties to avert or remedy harm through generosity and public service; and courage, which earlier Stoics had associated primarily with scorning danger and enduring pain, he analysed as a species of 'magnanimity' (literally 'greatness of soul'), which he argued finds its finest expression in constructive civil leadership, not military triumph. A similar emphasis on effective action over purity of motives appears in his account of temperance, where he shifted the focus from personal to social welfare by introducing a highly original analysis of 'propriety' (*prepon*, Latin *decorum*). Exploiting analogies with the theatre, he classified duties under four kinds of 'roles' (Latin *personae*): some duties apply universally because imposed by (1) human nature, but many vary individually because imposed by (2) individual capacities and temperament, (3) station and circumstance, or (4) our own deliberate choice. One aim of this schema was to guide deliberation by articulating the variables affecting what different people should do. But since propriety is achieved by balancing the obligations imposed by one's several roles, the schema also gave new weight to social and ethical diversity and showed more clearly how to achieve moral 'progress'.

Panaetius' account of propriety reflects his rejection of the asceticism and iconoclasm early Stoics had adopted from the Cynics. But his concessions to the more humane values of civility and urbanity also marked a major expansion of the scope of obligation and gave Stoic ethics a new and distinctly political orientation. While focused on personal conduct, his ethical theory articulates a paradigm of public service that imposes substantial social and political obligations on people of talent, wealth and influence, but reduces demands on those less favoured by birth or fortune. The result is a model of paternalism which Cicero and others exploited in order to justify the aristocratic institutions of Rome. Panaetius, whose life spanned the period when the formerly autonomous Greek states were reduced to Roman provinces, thus provided Romans with a framework for justifying imperialism in general, and Roman rule in particular, as a relation of mutual advantage that could foster peace, prosperity and political stability.

Pan-Africanism

Pan-Africanism covers a wide range of intellectual positions which share the assumption of some common cultural or political projects for both Africans and people of African descent. The political project is the unification of all Africans into a single African state, sometimes thought of as providing a homeland for the return of those in the African diaspora. More vaguely, many self-identified pan-Africanists have aimed to pursue projects of solidarity - some political, some literary or artistic - in Africa or the African diaspora. The Pan-Africanist movement was founded in the nineteenth century by intellectuals of African descent in the Caribbean and North America, who saw themselves as belonging to a single negro race. As a result the Africa of pan-Africanism has sometimes been limited to those regions of sub-Saharan Africa largely inhabited by darker-skinned peoples, thus excluding those lighter-skinned north Africans, most of whom speak Arabic as a first language.

In the twentieth century this racialized understanding of African identity has been challenged by many of the African intellectuals who took over the movement's leadership in the period after the Second World War. Founders of the Organization of African Unity, such as Gamal Abdel Nasser of Egypt and Kwame Nkrumah of Ghana had a notion of Africa that was continental. However, the movement's intellectual roots lie firmly in the racial understanding of Africa in the thought of the African-American and Afro-Caribbean intellectuals who founded it.

Pan-Africanism began as a movement in the diaspora among the descendants of the slave populations of the New World and spread to Africa itself. As a result the forms of solidarity it articulated aimed to challenge anti-black racism on two fronts: racial domination in the diaspora and racialized colonial domination in the African continent. The movement's fissures have occurred where these two clearly distinguishable projects have pulled it in different directions.

1 First formulations: W.E.B. Du Bois

The term *pan-Africanism* was coined around the time of the first pan-African congress in London in 1900. However, the idea of a form of solidarity of the negro race appeared in the nineteenth century. Like eastern European pan-slavism and the forms of nationalism that created modern Germany and Italy, these early forms of solidarity reflected a philosophical tradition derived from Herder in which peoples were the central participants in the creation of world history, expressed themselves in literature and folk culture and sought political expression in nation-states. The first black intellectual to produce a fully theorized account was W.E.B. Du Bois (1868-1963) in his paper 'The Conservation of Races' (1897) which was the second occasional paper to be published by the American Negro Academy and made use of the term *pan-negroism*. Du Bois studied with William James as an undergraduate at Harvard and went on to do graduate work at the University of Berlin. He was, therefore, familiar with the intellectual traditions of modern European nationalism and their philosophical underpinnings.

In 'The Conservation of Races' (1897) Du Bois argued that 'the history of the world is the history, not of individuals, but of groups, not of nations, but of races' (1897: 76). (He mentions Slavs, Teutons and the Romance race, indicating that, like so many other Western intellectuals of his day, he thought of real nations as races.) He argued that the differences between races were 'spiritual, psychical differences - undoubtedly based on the physical, but infinitely transcending them' (1897: 77). Also, he insisted (in a manner reminiscent of Herder) that each race was 'striving, each in its own way, to develop for civilization its particular message' (1897: 78).

The problem for pan-negroism thus framed was how negro people were to deliver their message.Du Bois was clear that African-Americans (whom he called the 'advance guard of the negro people' (1897: 79)) were to play the leading role in that task. He thought so because, although their ancestors had arrived in the New World as slaves, some like himself had been exposed to the best education and the highest forms of knowledge.

2 Nineteenth-century origins

Although Du Bois's formulation owed much to the intellectual ferment of European nationalism, it also had roots in the thought of a number of earlier African-American thinkers, whose work is best understood in the context of the broad nineteenth-century history of anti-slavery, or *abolitionist* thought. The focus of attention for all the major black thinkers in the New World in the early nineteenth century was the abolition of slavery and the slave trade.

As it was widely believed that racial antagonism between blacks and whites was inevitable (a common view explicitly held by US presidents Jefferson and Lincoln) one major preoccupation of some abolitionists was to find territories that could be inhabited by freed blacks. The colony of Sierra Leone was created in the late eighteenth century by UK abolitionists as a home for freed blacks and the black poor of the UK. The American Colonization Society played a similar role in the creation of Liberia in the 1820s. Other schemes were proposed to colonize parts of Latin America, the Caribbean and the US western frontier.

All of these schemes presupposed that Africans and their descendants in the New World belonged naturally together in a political community separated from other peoples. There were significant voices raised in protest against this assumption, notably that of the American ex-slave and abolitionist Frederick Douglass. They were joined by many others after the USA formally recognized the citizenship of people of African descent in the post-Civil War amendments to the US constitution. In the first half of the nineteenth century the majority view among white and black intellectuals was that a home was needed for the negroes if they were to be free.

Perhaps the three most important black intellectual ancestors of pan-Africanism were Martin R. Delany (1812-85), Alexander Crummell (1822-98) and Edward Wilmot Blyden (1832-1912). Martin Delany was born in southern USA, but his family moved to Pennsylvania during his youth. He began a medical education at Harvard, but was forced to leave by the refusal of white students to work alongside him. Delany's contributions to the prehistory of pan-Africanism began with a sense of a profound connection with Africa. He was proud that he was a 'full-blooded negro' and he named his children after Toussaint L'Ouverture, the black leader of the Haitian revolution, Ramses after the Egyptian Pharaoh and Alexandre Dumas after the French novelist who had some African ancestry. Delany was also a powerful voice for black emigration from the USA. He argued in *The Condition, Elevation, Emigration and Destiny of the Colored People of the United States* (1852) that only in a country without white people could black people flourish. In that early work, Delany refrained from making the obvious suggestion that blacks should travel to Africa. This was not because he was against the idea but because he and other leaders of the re-emigration movement believed that most African-Americans, convinced by anti-negro propaganda, were likely to see Africa as inhospitable. In his *Official Report of the Niger Valley Exploration Party* (1861), written after he had been to Africa, he wrote of the continent as 'our fatherland' and argued that its regeneration required the development of a 'national character'. He proposed the formula, 'Africa for the African race and black men to rule them' (Geiss 1974: 165), which is one of the earliest formulations of a pan-Africanist principle.

Alexander Crummell was born in New York and educated in the UK at Cambridge University, the first African-American to attend. He was also an ordained Anglican clergyman and the first African-American intellectual to spend a significant amount of time in Liberia. When Delany visited that country in 1859, he met Crummell who had been there by then for two decades. In *The Future of Africa: Being Addresses* (1862), a collection of essays and lectures written while he was in Liberia, Crummell developed a vision of Africa as the motherland of the negro race. In 'The English Language in Liberia' (1860a), based on a lecture given on Liberian independence day, he argued that African-Americans exiled in slavery to the New World, by divine providence had been given 'at least this one item of compensation, namely, the possession of the Anglo-Saxon tongue'. Similarly he argued for the providential nature of the transmission of Christianity to negro slaves, believing that it was the duty of 'free coloured men' in the USA to work for the Christianization of their ancestral continent. In the essay 'The Relations and Duties of Free Colored Men in America to Africa' (1860b), he expressed with great clarity the underlying racial basis of his understanding of negro identity, defining a race as 'a compact, homogeneous population of one blood ancestry and lineage' and arguing that each race had certain 'determinate proclivities' which manifested themselves in the behaviour of its members. Crummell, with Blyden, was one of the founders of Liberia College, later the University of Liberia. Unlike Blyden he did not become a permanent resident of Liberia. He returned rather to the USA where he continued to argue for the importance of an engagement with Africa on the part of blacks in the African diaspora. Crummell was the leading spirit in the foundation of the American Negro Academy and was present at the meeting at which Du Bois first read 'The Conservation of Races' (1897). He was a significant influence on Du Bois, who included an essay about Crummell in his influential publication *The Souls of Black Folk* (1903).

Edward Wilmot Blyden was born in the West Indies. He travelled to Liberia in 1850 under the auspices of the American Colonization Society. He became a citizen of that country for the rest of his life. Like Crummell, he was

a priest. Blyden was a polyglot scholar whose essays included quotations in the original languages from Alighieri, Dante, Virgil and Saint-Hilaire. He studied Arabic in order to teach it at Liberia College and later became the Liberian ambassador to Queen Victoria. In *Christianity, Islam and the Negro Race* (1887), first delivered as a lecture to the American Colonization Society in 1883, he too expressed the conviction that underlies Du Bois's first explicit formulation of pan-Africanism: 'Among the conclusions to which study and research are conducting philosophers, none is clearer than this - that each of the races of mankind has a specific character and specific work' (1887: 94).

Both Blyden and Crummell had little respect for the traditional cultures of Africa. They shared the conviction that the task of Christianized blacks of the diaspora owed a responsibility towards the conversion of their African cousins. Blyden argued that one could not deduce from Africa's 'state of barbarism' any innate deficiency in the negro. He observed that 'there is not a single mental or moral deficiency now existing among Africans - not a single practice now indulged in by them - to which we cannot find a parallel in the past history of Europe' (1887: 58). He was convinced that the negro race had an intrinsic affinity with religion and that the diffusion of Islam in west Africa had laid the groundwork for conversion to Christianity.

3 The pan-African congresses and the Garvey movement

If the intellectual ancestry of pan-Africanism is in the work of Du Bois, Delany, Crummell and Blyden, its institutional history begins with Sylvester Williams, a London barrister born in Trinidad. In 1897 he planned to bring together the 'African race' around the world. In July 1900, after a preliminary conference in 1899, such a gathering took place in London. There were four African representatives - one each from Ethiopia, Sierra Leone, Liberia and the Gold Coast colony - and around twelve from the USA, including Du Bois; eleven representatives came from the West Indies and five from London.

The conference opened with the aim of allowing black people to discuss the condition of the black race around the world. In 1921 Du Bois and others organized a second congress which met in three sessions in London, Brussels and Paris. This time there were representatives from Francophone and Lusophone Africa. A final declaration was issued which insisted on the equality of the races, the diffusion of democracy and the development of political institutions in the colonies. It also urged the return of negroes to their own countries and attention under the rubric of the League of Nations both to race relations in the industrialized world (the 'negro problem') and the condition of workers in the colonies. A third congress occurred in London in 1923 and continued in Lisbon. This second stage of the congress was more an opportunity for Du Bois to talk to some people from the Portuguese colonies on his way from London to Liberia where he was the official representative of the USA to preside over the installation of the Liberian president.

The Pan-African Congress movement disappeared until the fifth congress in Manchester in 1945 at which the continent took on a key role, as opposed to the diaspora. From there Du Bois's contribution was overshadowed by Kwame Nkrumah, who was to be Ghana's first prime minister. Du Bois was the only significant African-American present.

During the period between the First and Second World Wars when the Pan-African Congress movement was most active, sentiment received a substantial practical boost from the growth of the Garvey movement led by Marcus Garvey. He was a Jamaican immigrant to the USA, who developed his Universal Negro Improvement Association into the largest black movement in the African diaspora. The slogan of the movement was 'Back to Africa' and Garvey planned a shipping line for the purpose, although relatively few members of the organization actually left the New World for the Old. Garvey's commitment to racial pride and to the celebration of black historical achievement and his concern to link the diaspora to the continent make him an important figure in the movement's history.

4 George Padmore

George Padmore (1902-59), a West Indian-born intellectual played an important role in planning the congress in 1945. Born Malcolm Nurse, Padmore was a Trinidadian who spent time in the USA studying at Columbia University and Fisk, a black university which Du Bois also attended. Padmore worked for the Communist Party as an organizer among students at Howard University, the black university in Washington, DC. Later he spent time in

Germany and Russia, where he became the head of the Negro Bureau of the Red International of Labour Unions in 1930. In the next few years he worked for communist organizations in Austria and Germany, moving to London in 1935. From then until his death in 1959 he was the leading theorist of pan-Africanism and a close friend and adviser of Kwame Nkrumah. His *Pan-Africanism or Communism? The Coming Struggle for Africa* (1956) is probably the most important statement of his position.

5 Legacy

In the period after the Second World War African intellectuals were preoccupied with the question of independence. Once independence was attained, pan-Africanism became an ideology through which relations among the newly independent states could be thought about. Pan-Africanist rhetoric continues to be important in the language of the Organization of African Unity founded in 1963. In that same period, black intellectuals in North America were taken up with questions of civil rights. There were always resonances between these two projects - Du Bois was involved in both throughout his long life and died a citizen of Ghana. African diplomats sought to get civil rights questions raised in the forum of the United Nations, but pan-Africanism took philosophical form in the period leading up to Padmore’s work. Its major theoretical works are those of Padmore and Du Bois.

Panpsychism

Panpsychism is the thesis that physical nature is composed of individuals each of which is to some degree sentient. It is somewhat akin to hylozoism, but in place of the thesis of the pervasiveness of life in nature substitutes the pervasiveness of sentience, experience or, in a broad sense, consciousness. There are two distinct grounds on which panpsychism has been based. Some see it as the best explanation of the emergence of consciousness in the universe to say that it is, in fact, universally present, and that the high-level consciousness of humans and animals is the product of special patterns of that low-level consciousness or feeling which is universally present. The other ground on which panpsychism is argued for is that ordinary knowledge of the physical world is only of its structure and sensory effects on us, and that the most likely inner content which fills out this structure and produces these experiences is a system of patterns of sentient experience of a low level.

1 The nature of panpsychism

Through prejudice and misunderstanding, panpsychism is often thought a somewhat fanciful doctrine; thus commentators often try to save some admired master from association with it. Consequently, an uncontroversial list of panpsychists is problematic. Especially debated is the case of Spinoza, and there is some argument too over Whitehead, though certainly many process philosophers working in the Whitehead and Hartshorne tradition are panpsychists. Other thinkers either committed, or strongly inclined, to panpsychism include Gustav Fechner, R.H. Lotze, Friedrich Paulsen (d.1908) William James, Josiah Royce, C.H. Waddington (d.1975) and Charles Hartshorne. Leibniz, Schopenhauer and Bergson advanced positions akin to panpsychism.

Panpsychism is expressed somewhat variously in virtue of differing usages of such words as ‘consciousness’, ‘sentience’, ‘feeling’ and ‘experience’. Here we shall use the word ‘consciousness’ taken in a very broad sense. (Readers may mentally substitute ‘sentience’, if they prefer, provided they do not understand this purely behaviourally.) Any individual such that there is a truth *as to what it is like to be it* (in general or at some particular moment) is conscious, and its consciousness is what that truth concerns. I may have limited power to grasp what it is like to be you, but I cannot seriously doubt that there is something there to be right or wrong about, as sensible people think also true about animals (except perhaps the very simplest). But if I try to imagine what it is like to be this table here, everyone will agree that there is nothing there to be imagined.

The point is not that one’s conscious states must be like something, must have a character; that is true of everything. But things do divide, in common opinion, into those such that there is and those such that there is not *something that it is like to be them* (though this expression is only an idiomatic pointer to something it requires a certain sophisticated obtuseness to be unable to identify).

The paradigm panpsychist maintains that each of the ultimate units of the physical world (whether particles, events or even mutually influencing fields) out of which all other physical things are made, are conscious in this sense. Of course, they are not self conscious, or thoughtful, but each has some dumb feeling of its own existence and of its exchange of influence with other things. It does not follow, they will rightly insist, that every physical thing is conscious. Many things, such as sticks and stones, made of these ultimate units are not so. Thus while a stone will be composed of conscious units without itself being conscious, a waking human brain will both itself be conscious and be composed of what is conscious, perhaps at two levels (for example, the neurons in the brain may be individually conscious and also made up, like everything else, of ultimate physical units which are so). Hence panpsychism, as such, leaves open the question as to which individuals above the minimal scale are sentient and which not, though particular systems of panpsychism may have their own suggestions as to how this can be decided. (Some think an element of behavioural spontaneity is its chief external mark.)

2 Arguments for panpsychism

The first argument for panpsychism is that it can ground the best account of how something so apparently novel as consciousness could have arisen within a physical world whose development has otherwise been simply a re-arrangement of the homogeneous. One theory based on this argument is that the experience of those non-ultimate units in nature which are conscious are literally composed of the experiences of their ultimate parts. Thus my experience consists in the experiences of my neurons (and those of the experiences of their ultimate

parts) which unite in a way in which the experiences of the parts of non-conscious things do not. Thus nothing essentially novel has come into the universe with human or animal consciousness, only new solidifications of the consciousness (sometimes called 'mind dust') already pervasive in the universe.

This is not a very satisfactory view. For consciousness seems to exist only in distinct individual units or 'centres', and it seems doubtful that these can combine to make more comprehensive ones. Even if this is not in principle impossible (and some panpsychists have reasons for thinking it possible in principle), introspection of our own consciousness hardly suggests that any of its components have a distinct sense of their own being.

However, there are various ways in which the theory may be made more promising. Perhaps it is a law of mental nature that when conscious individuals form a system of a certain type, that system becomes conscious in its own right so that its behaviour is due to a combination of the mental states of its parts and its mental state as a whole, without the latter strictly being composed of the former. If so, the emergence of high-level consciousness like ours is due to laws concerning the 'charge' of consciousness associated with matter in general rather than the result of its purely physical character, and thereby seems more intelligible.

The panpsychism we have considered so far implies no particular view of the nature of physical reality. It simply holds that each ultimate unit of the physical world has a certain 'charge' of sentience, which is additional to its physical characteristics, and that in certain circumstances more complex units of nature receive their own individual 'charge' of sentience too.

The second argument for panpsychism favours the different conclusion that consciousness is the real 'stuff' of the physical universe (though this may be further reinforced by the first argument). It starts with the claim that, metaphysics apart, we only know the structure of physical things as such (and of the physical world in general) and their sensory effects on centres of consciousness like ourselves - identified as the consciousness pertaining to certain complex physical things similarly specified - not the content in which that structure is realized concretely. Thus our knowledge of physical reality, so far as it goes beyond characterizations of things simply as the cause of certain sensations in ourselves, is rather like the kind of knowledge of a piece of music which someone born deaf might have from a musical education based entirely on the study of musical scores, such as could lead them to play (perhaps somewhat lifelessly) compositions on the piano without having any idea of the specific quality of heard sound in general or of the particular sounds currently being produced.

It being acknowledged that (metaphysics apart) we only know the structure of physical reality (or only the structure and the experiences it produces in us), a speculative mind will wonder whether its qualitative nature must remain entirely unknown. They will reflect that there is one kind of thing, after all, of which we do know the inherent quality, namely our own consciousness and, by inference, also the consciousness of other humans and to a limited extent animals. In short, we know the generic nature of consciousness and a good deal about the specific forms it can take. Moreover, we are incapable even of conceiving in any genuinely full way any thing more than a mere abstract structure (needing to be embodied in something more concrete to exist) which is not a form or a content of consciousness. (This is an essentially idealist claim which cannot be examined here: see Idealism §2.) Could this be because what we call the generic essence of consciousness is in fact the generic essence of all possible fully concrete reality? If so, the reality which produces 'perceptual' experiences in us, and the structure of which science (and less precisely, common sense) aspires to formulate and control, must somehow be composed of consciousness. This is at least a hypothesis worth exploring as the only alternative to saying that matter is unknowable in its inner essence, and as likely also to cast light on the mind-body or mind-brain relationship.

3 Consciousness in panpsychism

But how can consciousness have that kind of structure? The simplest hypothesis is that there are innumerable interacting centres of consciousness which are the inner being of nature's ultimate physical units; that there are definite lines of possible influence between them, either connecting them immediately or through 'intervening' ones; and that the 'geometry' of these lines is more or less adequately represented by what we conceive of as their spatial or spatiotemporal relations (or those of complexes including them), while a description of any particular physical process is thus a purely structural account - supplemented by an indication of how it is liable to affect our own perceptual experiences - of the way in which these possible influences have become actual.

However, there are various alternative paths which an attempt to understand the world panpsychistically may take.

In particular, there are alternative accounts of how the over-all or dominant consciousness of a human being (such as is calling itself 'I' when one speaks) or animal fits into the scheme. The hypothesis just described suggests that the laws which govern the interaction of such a dominant centre of consciousness with the lower-level centres of consciousness which constitute its body, and via that with other things, are distinct from those which govern those interactions between lower-level centres of consciousness which constitute more 'purely physical' processes both within its body and in nature at large. This has a certain kinship to dualism since, though mind and matter are ultimately the same kind of 'stuff', fresh laws of interaction apply where centres of consciousness of a higher level than those present throughout nature come into operation (see Dualism §5). Also it is likely to conceive the spatial location of such a dominant centre of consciousness as more diffuse than that of the physical units corresponding to the centres which it dominates. (In principle, it can recognize wholes other than animals with a similarly dominant consciousness diffusely existing within them.)

However, other forms of panpsychism try to fit our consciousness into a world of interacting centres of consciousness whose structural description remains solely that of universal physics. These have some kinship with 'double aspect' conceptions of mind and brain. Various further versions of panpsychism are possible too, all sharing the claimed advantage of conceiving the mind-brain relation as a relation between things which are of the same generic kind. Actually, panpsychists have tended to develop their theories on the basis of an event or process ontology rather than that of individual continuants which endure through a certain length of time, so that for them the natural world in its inner being consists of innumerable streams of interacting experience rather than of interacting sentient continuants. Panpsychism is also sometimes associated with some form of absolute idealism according to which all things are included in one all-embracing consciousness in a manner which displays itself as their containment in a single spatiotemporal system.

Pan-Slavism

In B.H. Sumner's words: 'Since Pan-Slavism was in general not so much an organized policy, or even a creed, but rather an attitude of mind and feeling, it was at the time correspondingly difficult to gauge its power, just as it is now to analyse its different elements' (Sumner 1937). Logically and philosophically weak, and in fact usually deficient in any kind of intellectual structure, this identification with, preference for, and emphasis on the Slavs has, nevertheless, been a presence in European (and to a much lesser extent world) history ever since its emergence in early nineteenth century.

1 Origins

While modern Pan-Slavism had some interesting predecessors, such as the seventeenth-century Croat and Roman Catholic priest Juraj Križanić who spent many years in Russia and advocated Slav unity under the Muscovite tsar, its own emergence should be dated from the first part of the nineteenth century. It was produced by two related intellectual and cultural phenomena: the new Romantic ideology centred on organicism and, increasingly, historicism; and the establishment of modern philology. The first provided the fundamental worldview for at least the early stages of Pan-Slavism; the second pinpointed the object of allegiance and devotion, the organism to which one belonged, namely Slavdom as attested by the use of a Slav language. Some pioneers of new thought, notably Herder, not only provided the necessary framework for Pan-Slavism, but also themselves dealt favourably with the Slavs. Ironically, that new thought, although many-sided, rich, and eventually as extensive as Western civilization itself, could also be regarded as most especially German.

2 Pan-Slavism in central and eastern Europe

Very much in the spirit of the age, Pan-Slav ideas eventually influenced Slav intellectuals wherever they could be found, including the small and isolated Sorbian communities in Saxony. Even the briefest account must mention developments in four large areas: the Czech and Slovak territories of the Habsburg Empire; Illyrian or South Slav lands (the latter being another crucial linguistic designation, although in fact it omitted Bulgaria), both inside the Habsburg state as in the cases of the Croats and the Slovenes, and outside it as in the case of most of the Serbs; divided Poland; and Russia.

In this climate of ill-defined hopes and dreams nationalism took hold of two young Lutheran Slovaks who may be regarded as the fathers of early Pan-Slavism, Jan Kollár (1793-1852) and Pavel Josef Šafařík (1795-1861). Kollár became its first poet, Safarík its first scholar. Kollár's inspiration came directly from his student years at the University of Jena, 1817-19, and represented both a faithful reproduction of the new German Romantic nationalism and its transformation into a Slav one, in opposition to the German. The two pioneers were followed by numerous other enthusiasts including the indefatigable writer Ludevít Stúr (1815-56) and the historian Frantisek Palacký (1798-1876), who 'construed Czech history as a struggle between the peace-loving, naturally democratic Slavs and the bellicose and aristocratic Germans' (Kohn 1953: 24). Different kinds of Slavs constituted almost half of the population of the Habsburg Empire, and Slav issues were bound to be prominent in its politics, especially in the age of nationalism. The revolutionary years of 1848 and 1849 witnessed such developments as a revolution in Prague, as well as in Vienna and in Budapest, an abortive Pan-Slav congress in Prague, and Croat support of the Habsburgs in their war against the Hungarians. The settlement of 1867 transformed the state into a dual entity, Austrian-German and Hungarian, increasing Slav dissatisfaction and also suggesting further change into a triune body, the Slavs finally becoming equal to the two dominant nationalities. But other possibilities were pre-empted by the First World War and the resulting collapse of the Habsburg Empire. That war, of course, was significantly related, both in its immediate origins and in its more fundamental causes, to Slav, even Pan-Slav, issues.

Backward in terms of education and participation in general European culture, in fact many of them oriented for centuries more towards Istanbul than towards Vienna, the South Slavs too began to be affected by Pan-Slavism. Ljudevit Gaj (1809-72) was the moving spirit of this Illyrism, later Yugoslavism (South Slavism). A Croat, educated in Graz and Budapest, influenced by Kollár and active especially in Zagreb, Gaj produced a *Short Outline of Croat-Slovene Orthography* which did much to establish the modern unified Serbo-Croatian literary language, which the author used to publish the first Croatian newspaper and even to create the Croatian national

anthem. Croat-centred Yugoslavism was further developed by the Roman Catholic bishop Josip Juraj Strossmayer (1815-1905) and other Zagreb intellectuals. But other South Slavs were less responsive. The Serbs, following Vuk StefanovićKaradžić (1787-1867), writer and language reformer, and other pioneers, stressed their own nationalism and looked at contemporary Serbia as the Piedmont of the South Slavs, who were to be brought together in the great Serbia of the future. Even the representatives of the small Slovene people, animated by their poet France Prešeren (1800-49), emphasized Slovene cultural distinctiveness and considered themselves loyal Austro-Slavs. As to the Bulgarian awakening, promoted especially by Iurii Hutsa (1802-39), better known after his change of name as Iurii Ivanovich Venelin, it consisted mainly in a certain emancipation from the Greek ecclesiastical and intellectual domination and a bid for a mighty Bulgaria sponsored by Russia.

Whereas South Slavs, and some other Slavs as well, can be described as ‘awakening’ in the first decades of the nineteenth century, Poland was then experiencing a literary and intellectual renaissance of world significance. The disparity makes all comparisons inadequate. Such thinkers as Stanislaw Staszic (1755-1826), Josef Marie Hoene-Wroński (1778-1853), August Cieszkowski (1814-94), Bronislaw Trentowski (1808-69) and the historian Joachim Lelewel (1786-1861), together with such great writers and poets as Adam Mickiewicz (1789-1855), Juljusz Slowacki (1809-49) and Zygmunt Krasiński (1812-59), focused explosively their Slav, and indeed Pan-Slav, themes on the historic and contemporary tragedy of Poland and in particular on its relations with Russia. Suggested remedies ranged from wise leadership of Slavdom by the Russian tsar to hopes for a revolutionary and democratic Russia united with a similar Poland, and to still more unreal messianic and apocalyptic visions - often accompanied by some of the most brilliant denunciations and criticisms of Russia and the Russians ever made. Moreover, Polish messianic thought easily burst the boundaries of Slavdom, presenting Poland as the redeemer of the world, ’Christ of the nations’.

3 Pan-Slavism in Russia

In contrast to Habsburg Slavs or Poles, Russians (or at least Great Russians, not to prejudge the complex and evolving issues of Ukrainian and Belorussian nationalisms) did not live in a state dominated by other nationalities. Nor was the Russian Empire a marginal Balkan principality. Indeed Russia stood out as the only Slav world power, the beacon of expectation and hope for many non-Russian as well as Russian Pan-Slavs. Yet, in spite of its impressively advantageous position, Russian Pan-Slavism both in its nature and its historical role bore a striking resemblance to its counterparts west and south of the Russian borders. Derived from German Romanticism, ’Slav’ themes were ably developed by a number of Russian intellectuals, meshing well with a certain sympathy for the Slavs (not the Poles, however), in particular as against Turkey and later the Germanic empires, present in the broader Russian public. Yet Pan-Slav intentions were usually at cross-purposes with government policy, and Russian Pan-Slavism remained characteristically a matter of sentiment - and at times a bugbear to ill-informed foreigners - but not an effective force.

The Slavophiles, who constructed the most comprehensive and the most creative Russian Romantic ideology, are of special interest for the ’Slav’ theme (see Slavophilism). The leading members of the group, all of them landlords and gentlemen-scholars of broad culture and many intellectual interests, included Aleksei Stepanovich Khomiakov (1804-60), who applied himself to everything from theology and world history to medicine and technical inventions, Ivan Vasil’evich Kireevskii (1806-56) who has been called the philosopher of the movement, his brother Pëtr Vasil’evich Kireevskii (1808-56) who collected folk songs and left very little behind him in writing, Konstantin Sergeevich Aksakov (1817-60), a specialist in Russian history and language, his brother Ivan Sergeevich Aksakov (1823-86), later prominent as a publicist and a Pan-Slav, and Iurii Fëdorovich Samarin (1819-76), who was to have a significant part in the emancipation of the serfs and wrote especially on certain religious and philosophical topics, on the problem of the borderlands of the empire, and on the issue of reform in Russia. This informal group, gathering in the salons and homes of Moscow, flourished in the 1840s and 1850s until the death of the Kireevskii brothers in 1856 and of Khomiakov and Konstantin Aksakov in 1860.

Slavophilism expressed a fundamental vision of integration, peace and harmony among human beings. On the religious plane it produced Khomiakov’s concept of *sobornost’*, an association in love, freedom, and truth of believers, which Khomiakov considered the essence of Orthodoxy. Historically, so the Slavophiles asserted, a similar harmonious integration of individuals could be found in the social life of the Slavs, notably in the peasant commune - described as a ’moral choir’ by Konstantin Aksakov - and in such other ancient Russian institutions as

the *zemskii sobor* (a kind of Muscovite estates general to advise the tsar). Again, the family represented the principle of integration in love, and the same spirit could pervade other associations of human beings. As against love, freedom and cooperation stood the world of rationalism, necessity and compulsion. It too existed on many planes, from the religious and metaphysical to that of everyday life. Thus it manifested itself in the Roman Catholic Church - which had chosen rationalism and authority in preference to love and freedom and had seceded from Orthodox Christendom - and, through the Catholic Church, in Protestantism and in the entire civilization of the West. Moreover, Peter the Great introduced the principles of rationalism, legalism, and compulsion into Russia, where they proceeded to destroy or stunt the harmonious native development and to seduce the educated public (see Enlightenment, Russian §1). The Russian future lay in a return to native principles, in overcoming the Western disease. After being cured, Russia would take its message of harmony and salvation to the discordant and dying West. The all-embracing Slavophile dichotomy represented - as pointed out by F. Stepun and others - the basic romantic contrast between the romantic ideal and the Age of Reason. As to Russian Pan-Slavism, the Slavophiles should be considered its important predecessors rather than its fully-fledged adherents. The Slavs never occupied a central position in their teaching, and in fact had only a minor and superficial connection with Khomiakov's theology and none at all with Ivan Kireevskii's philosophy. Yet other members of the group, and even the same Khomiakov, developed popular 'Slav' themes in prose and poetry, glorifying their imaginary ancestors and brothers, and providing one of the most decisive and far-reaching criticisms of the West available. There was a certain logic to Ivan Aksakov's becoming, later in the century, a leader of a genuine Pan-Slav movement. (Professor S. Lukashevich even suggested that he did so after he concluded that a titanic war between the Slavs and the Germans would shake Russia to its very depths and thus bring about the return to the old Russian spirit and principles and the end of the 'Western', Petrine period of Russian history - a crucially important transformation, unaccounted for in the original Slavophile theory.)

'Slav' and even Pan-Slav ideas were also propounded by certain adherents to the government ideology which came to be known as Official Nationality, such as Professors Mikhail Petrovich Pogodin (1800-75) and Stepan Petrovich Shevyrev (1806-64), although never by Tsar Nicholas I himself or his immediate assistants. Other enthusiasts included two great literary figures, the poet Fëdor Ivanovich Tiutchev (1803-73) and, later, the novelist Fëdor Mikhailovich Dostoevskii (1821-81), as well as a number of lesser writers. Russian Pan-Slavism even acquired a remarkable supporter on the extreme left: Mikhail Aleksandrovich Bakunin (1814-76), 'founder of nihilism and apostle of anarchy', who believed in the great revolutionary potential of the Slavs and participated in the Pan-Slav congress in Prague in 1848 and some other revolutionary events of those years.

The Russian Pan-Slav movement of the second half of the nineteenth century is usually traced to the Moscow Slav Benevolent Committee founded in January 1858 and to its later sections or more autonomous organizations in such cities as St Petersburg, Kiev and Odessa. The committees devoted themselves to cultural and philanthropic enterprises such as scholarships for Balkan students in Russia and some financial aid to schools and churches in the Orthodox parts of the Ottoman and Habsburg Empires. They also served as a fulcrum for Pan-Slav thought, with special emphasis on the Russian language as the obvious common language for the Pan-Slav world. A Pan-Slav congress was held in Moscow in 1867, with eighty-one Slav guests from abroad, but it produced no tangible results, the question of Poland remaining the most intractable divisive issue. Russian Pan-Slavism experienced a great revival during the Balkan Wars of the late 1870s as thousands of Russian volunteers flocked to fight for the Bulgarians and the Serbs against the Turks before Russia itself joined the fray. But if the Treaty of San Stefano of 1878 could be considered the high point for Russian Slav sentiments and Pan-Slavism, its remaking that same year at the Congress of Berlin came as a sharp disappointment. Slav and Pan-Slav sentiments also rose occasionally later in connection with major events in the Balkans. The First World War itself became inevitable when Russia came to the aid of Serbia against Austria-Hungary. Bulgaria, however, chose to fight on the opposite side, Habsburg Slavs provided manpower for the Habsburg armies, although some of them went over to the Russians, while Poland remained a problem for the Russian Empire until its dying day.

Together with world politics, the intellectual climate also changed. Whereas Pan-Slavism stemmed from Romanticism and developed for decades within the Romantic framework, in the second half of the nineteenth century it came to be influenced and even dominated by new trends of thought: 'realistic' (as in *realpolitik*), pragmatic and at the same time scientistic, that is, applying (or rather misapplying) scientific categories to human society and history. Danilevskii's *Rossiia i Evropa*, published in the periodical press from 1869 and as a book first

in 1871, and frequently referred to as the Bible of Pan-Slavism, may be considered the epitome of the new approach. An able natural scientist, Nikolai Iakovlevich Danilevskii (1822-85) concluded that universal history and culture were delusions and that the only reality consisted in the existence and evolution of entirely separate linguistic-ethnographic entities. He discovered about a dozen such entities as well as some peoples who did not properly belong to history, because they offered either nothing or only destruction. Five laws were basic to the historical process: (1) language identified race or family of peoples; (2) for its particular civilization to develop that entity had to have political independence; (3) the basic principles of each entity were unique and could not be transmitted to another cultural-historical type; (4) to obtain the full richness of development each entity should be a federation of states and not absorbed by one of them; (5) as in the case of perennial monocarpic plants the period of growth of these cultural-historical types was indefinite, but the florescence and fruition of each occurred briefly and only once. The next step in history was to be the replacement of the Romano-Germanic, or European, by the Slav type, led, of course, by Russia - for in the visions of Ivan Aksakov and other Pan-Slavs a titanic war loomed on the horizon. Once successful, the Slavs could well institute the first society harmoniously synthesizing all four main aspects of human activity: the religious, the cultural, the political and the socioeconomic (it is especially in this last respect that the earlier cultural-historical types had proven so far deficient). In the meantime only Slav success mattered, not chimeras of universal civilization, universal standards or humanity itself.

4 Historical character and significance

At least so far Pan-Slavism has proven abortive as it failed in its expressed aim of uniting the Slavs, let alone of inaugurating a new Slav age of European and world history. The fortuitous circumstance that all Slavs found themselves, after the Second World War, within the confines of the Soviet Union or its East European satellites was but a vicious travesty of the Pan-Slav ideal, because that ideal could not even be expressed in the new regime, except in a highly circumscribed manner and in subservience to quite different beliefs of the new rulers. Nor did communist unity survive.

Reasons for the failure of Pan-Slavism are not difficult to find. A destabilizing and destructive doctrine, it had to challenge continuously the establishment, or rather establishments. Hence Austro-Slavism, which reflected both the restrictions on Pan-Slavism in the Habsburg state and the willingness of many Slavs to accommodate themselves to these restrictions at the expense of broader Pan-Slav vistas. In Russia the Pan-Slavs never captured the government and could only very occasionally provide valuable support for it or throw significant obstacles in its path. Old religions were often at cross purposes with Pan-Slavism. Thus the Russian emphasis on Orthodoxy or the Polish on Roman Catholicism frequently alienated and even antagonized Slavs who adhered to other creeds. Moreover, Pan-Slavism proved to be only one of the secular beliefs in modern European history, and not the most powerful one. Its overwhelming rival has been nationalism. The two are remarkably similar in their irrationality, romantic origins, linguistic emphasis and organicism. However, Romantic nationalism demands allegiance to the so-to-speak primary, ’national’ group, while Pan-Slavism and its counterparts direct it to the larger, secondary group, ’tribal’, more broadly ethnic or ’racial’. And it is to the primary group that the allegiance has been going. Thus Bulgaria fought a whole series of wars with Serbia; Ukrainian nationalism rose in opposition to Poland and Russia; Russian-Polish relations hardly need comment; even more telling may be the collapse of Yugoslavia (not Pan-Slav, to be sure, but nevertheless a secondary formation, for it aimed to bring at least the South Slavs together) in Croatian and Serbian massacres.

Pantheism

Pantheism contrasts with monotheism (there is one God), polytheism (there are many gods), deism (God created the world in such a way that it is capable of existing and operating on its own, which God then allows it to do) and panentheism (in God there is a primordial and unchanging nature, and a consequent nature that changes and develops). Etymologically, pantheism is the view that Deity and Cosmos are identical. Theologically, it embraces divine immanence while rejecting divine transcendence. If atheism is the denial that anything is divine, pantheism is not atheism; if atheism is the claim that there is no Creator, Providence, transcendent Deity, or personal God, pantheism is atheistic.

Spinoza, perhaps the paradigm figure for pantheism, was described by some as 'a God-intoxicated man' and by others as an atheist. On his account, only God or Nature *exists, a single, necessarily existing substance whose modes and qualities exhaust reality. Conceivable equally properly as physical or as mental, God or Nature is no proper object of worship, creates nothing, grants freedom to none, hears no prayer, and does not act in history. Personal immortality, on Spinoza's view, not only does not occur, but is logically impossible. It is one thing to value nature so highly that one calls it a divinity, another to believe in God in any monotheistic sense.*

This much said, it must be admitted that 'pantheism' is not easy to define precisely. As conceived here, pantheism need not be a variety of materialism, and if it is materialistic it includes a high view of the worth of matter. Yet 'pantheism' has served as a term of abuse, and as another term for 'atheism' and 'materialism' and 'deism', terms bearing quite different senses.

1 God and world

Within a pantheistic perspective, God is not conceived as transcending the universe and so is not thought of as Creator or Providence, cause of the world though distinct from it, an agent who affects history, or a comprehending hearer of prayer and receiver of worship. There is nothing not part of the world on which the world might depend. Monotheism means by 'world', roughly, 'whatever exists besides God' and this makes possible its claim that the world depends for its existence on God while God exists independently. Pantheism means by 'world' simply 'all there is' with nothing left over, and hence rejects any Creator/creature distinction. From a monotheistic standpoint, this is atheism, however valuable the pantheist may conceive everything, or each thing, to be (see Atheism §1).

Nor, in contrast with polytheism, does pantheism view nature as coming under the control of various beings, each with limited capacities and knowledge. Polytheistic deities are gods and goddesses of limited capacities, but they are typically conceived as possessing a transcendence of nature incompatible with pantheism. Further, pantheism is a radical type of monism, holding both that there is, strictly, only one thing, however many and diverse its interlocking elements, and one fundamental kind of thing (see Monism). Thus not only the distinction between Creator and creation, in which the former transcends the latter, but such distinctions as soul and body, concrete and abstract, and immaterial and material, seen as identifications of kinds of things such that anything belonging to one kind cannot belong to the other, are rejected.

2 Varieties of pantheism

Historical views often identified as pantheistic include Hesiod's *Theogony* and Stoicism, with its doctrine that God is a rational spirit who, shapeless himself, makes himself into all things, and its view of God as the tension or tendency to coherence that holds together the various sorts of things that there are, each sort itself defined in terms of its degree of internal tension or coherence (see Hesiod; Stoicism §§3-5). Xenophanes (§3) arguably viewed the cosmos as a living, conscious, divine unity. The Upaniṣads (800 BC and later) contain passages in which Brahman is represented as claiming identity with all sorts of things. The pantheistic and polytheistic tendencies expressed in the Upaniṣads are countered by other passages that offer a more monotheistic view and a tendency in Hinduism to henotheism. Advaita Vedānta Hinduism, represented classically by Śaōkara, holds that there exists only qualityless Brahman, a view similar to Schelling's (see Schelling, F.W.J. von §2; Vedānta). Johannes Scottus Eriugena (§3) held that anything exists only in so far as it participates in the essence of God, but he also insisted that no term applicable to creatures can be predicated of God. Fichte (§§6-7) thought of the world as the material through which

the Ego achieves its moral work, and identified the divine with a moral order that is composed of Ego and world. Giordano Bruno (§5) held God to be distinct from finite individuals only by including them within God's being, and followed Hermetic writings in making the unity of the All in the One a basic theme of his own thought (see Hermetism). Meister Eckhart, Boehme and Hegel (§§3-5) are not infrequently read pantheistically. Benedict de Spinoza's philosophy is a particularly fully developed and influential version of pantheism (see Spinoza, B. de §§2-4).

3 Two routes to pantheism

One might arrive at a pantheistic view of things by first believing that a self-conscious ontologically independent being exists, and then coming to think that if *B* depends for its very existence on *A* then *B* is part of *A* or *B* is in some other manner not a distinct being from *A*. Then one would have started as a monotheist and ended as a pantheist. This process will be helped along if one also thinks that if *B* depends for its very existence on *A*, then for any quality *Q* that *B* has, *B* has *Q* only because *A* causes *B* to have *Q*. Monotheism plus determinism plus the view that dependence rules out distinctness will yield pantheism. This is one route.

A different possible route goes in the opposite direction, as it were. If one believes that everything that exists depends every moment for its existence on something else, that everything that exists is valuable by virtue of simply existing, and that dependence rules out distinctness, then one will presumably conclude that there exists but one organic thing and (at least if one believes that valuable parts guarantee a valuable whole or else that the whole itself is valuable just by virtue of its existing) that this one thing is valuable. If one thinks very highly of its value, one may express one's view by saying that it is divine, using 'divine' in some such sense as 'possesses the highest possible value'. It is perhaps in this attitude that pantheism contrasts with atheism, in so far as there is a contrast.

4 Spinoza: God or Nature

Either route will leave one in the position of thinking that there is one whole composed of intimately related and interdependent parts. One rather precise way of putting this doctrine was developed by Spinoza. Spinoza's complex views, classically expressed in his *Ethics* (1677) come to something like the following. *God or Nature* is the only thing that exists. It is a substance - a possessor of states and properties and not itself a state or property. It has logically necessary existence, and each item that exists that is not identical to God or Nature is a mode or state of it, or a characteristic of it. Causal connections are properly understand as matters of, or at least as somehow isomorphic with, logical entailments. God or Nature is described as 'cause of itself', but this is not intended literally. It is Spinoza's way, not of saying that God or Nature both does not exist (so that its existence can be caused) and does exist (in order to do the causing), but that it is logically impossible that God or Nature should not exist or should depend for existence on anything.

Spinoza thinks that fatalism is true - any true proposition is necessarily true and any false proposition is necessarily false. Thus nothing that does exist could possibly have failed to exist, and nothing that does not exist could possibly have existed. Thus, while Leibniz and a great many other philosophers have talked about and thought in terms of possible worlds, believing that there is an infinite number of ways things might have been, for Spinoza there is not a multiplicity of possible worlds. There is exactly one way that things might have been, and that is the way things are; possibility is necessarily coextensive with actuality. Any characteristic that any state of God or Nature has is one that it could not possibly not have had, and any characteristic that any state of God or Nature lacks is one that it could not possibly not have lacked. Hence true natural science should be conceived of as analogous to the geometrician Euclid's *Elements*, which itself is conceived of as consisting of necessarily true axioms and necessarily true theorems that necessarily follow from the axioms. True physics is a fully developed deductive (every axiomatic truth is included and every derivable theorem has been derived) system whose axioms are necessarily true, and physical reality is isomorphic with true physics. Psychology, the science of mental states, is also a fully developed deductive system whose axioms are necessarily true.

God or Nature can be conceived under the attribute of extension, as what exactly corresponds to the true physics. God or Nature can also be conceived under the attribute of thought, as what exactly corresponds to the true psychology. Each way of conceiving it is entirely correct and leaves nothing out, save the fact that there is another equally exhaustive way of correctly describing and explaining things. Along with the various attributes and their corresponding theories, there is a set of notions - substance, attribute, mode, cause, finite, infinite, and the like -

that are involved in one's conceiving anything under any attribute, and thus that are in principle core concepts in any theory.

Indeed, Spinoza thinks that while we are able to conceive of only two attributes of God or Nature, there is an infinite number of attributes, to each of which in principle corresponds an exhaustive description of everything and an explanation of everything it is logically possible to explain, and each of which has its own core concept that plays within it the same role that extension and thought play in the theories they are central to. While 'being a body' and 'being a mind', then, are kind-defining features for Spinoza, he denies that they define ontologically incompatible kinds. Rather, he holds, they define exhaustive accounts of things, neither of which can be translated into the other, and each of which gives an account of the same thing as the other; necessarily connotatively incommensurate, they are necessarily denotatively identical. The resulting view is neither materialism, which would require that the true physics be the whole story, nor idealism, which would require that the true psychology be the whole story.

5 Consequences

Several consequences follow from a pantheistic perspective:

(1) *Regarding freedom*. A person is *categorically free* regarding an action if and only if, under prevailing conditions, they have the power both to perform and to refrain from performing it, and, whichever they do, they do not make false a law of logic or of nature, or some truth about the past. No one can possess categorical freedom if pantheism is true. This consequence is especially clear for Spinoza's version; his epigram is that freedom is only ignorance of causes. Human freedom presupposes logically possible alternatives to what is done, and according to Spinoza there are none. Divine freedom is a matter of none of the characteristics of God or Nature following from any essence but God or Nature's own (see Freedom, divine §§1-2). What is valued for humans is an understanding of the nature of things, joined with equanimity in accepting truths as necessary truths. In other varieties of pantheism, too, possessing freedom requires a separateness and autonomy hard to reconcile with pantheistic metaphysics. A categorically free agent is independent in the sense that they can so act as to determine some of their own properties in a manner not already determined by the situations and properties of other things. The unity that pantheism posits arises from everything depending for its existence and its properties on the existence and properties of other things (or on everything else depending for its existence and properties on one thing). States of a substance, parts of an organism, are not categorically free agents, even if the substance or organism is all-encompassing.

(2) *Regarding immortality*. Another consequence concerns individual immortality. In Spinoza's version, individual survival is logically impossible. Martha's body is a state or mode of God or Nature conceived under the attribute of extension. It is identical to what can also be described as Martha's mind or soul, which is the same mode as Martha's body, though now considered under the attribute of thought. Martha's body ultimately dies and disintegrates; hence it necessarily dies and disintegrates. Since Martha's mind or soul is identical to Martha's body, Martha's mind or soul ceases to exist when Martha's body ceases to exist. Spinozistic 'immortality' is a matter of what Martha knew corresponding to a part of what God or Nature conceived under the attribute of thought knows, and of Martha's material remains being composed of physical stuff that is part of what makes up God or Nature conceived under the attribute of extension. Spinoza is thus committed to the problematic view that necessarily, and hence either eternally or everlastingly, true propositions can entail propositions that specify particular temporal limitations, such as 'Martha exists from the date of her birth to the date of her death, neither before the one nor after the other'. 'The one substance there is necessarily exists' must, regarding its finite modes, entail propositions having the form 'Mode M exists only for a while'.

Even in pantheism's non-Spinozistic varieties, individual persons are conceived as so related to both other persons and to things that the very existential dependence and causal interaction that constitutes or yields their unity (that makes things *pan*theistic) militates against any ontologically deep individuality at any time. The at least potential separateness of a person from their body and natural environment, of the sort that doctrines of individual survival typically presuppose, is inconsistent with a pantheistic conception of things (see Soul, nature and immortality of the §2).

(3) *Regarding error and evil*. It is Spinoza's view that all error is simply confusion; what is false is

self-contradictory and thus, he believes, cannot be thought. The closest, then, it is possible to come to error is that one only confusedly understands the truth. There can be no such thing as false belief. Similarly, there is no room for genuine evil. What is, necessarily is, and the distinctions we make between good and evil have no purchase on a world in which it is logically impossible that anything be different.

Even if there are logically contingent truths, if everything is thought of as divine there is pressure to deny that anyone actually believes erroneously or that anything is genuinely evil (intellectual error itself may be seen as one variety of evil). Admittedly, dependence and lack of clarity are not perfections, but a pantheist can claim that they (in contrast to error and evil) are inevitable concomitants of being less than the whole. Thus while God or Nature cannot be evil, and God or Nature is all there is, a mode may seem defective considered by itself, but were it considered in the full context of its necessary existence as part of a system of modes and hence as part of God or Nature, its apparent defectiveness would vanish. Neither can there be sin, and so there can be no need for divine forgiveness (see Evil §3).

Spinoza’s statement of pantheism allows one to see what it entails. *Mutatis mutandis*, similar conclusions regarding freedom, personal immortality, and error and evil are likely to follow from other versions of pantheism.

Paracelsus (Philippus Aureolus Theophrastus Bombastus von Hohenheim) (1493-1541)

Paracelsus (pseudonym of Theophrastus Bombastus von Hohenheim) was an itinerant Swiss surgeon and physician who formulated a new philosophy of medicine based on a combination of chemistry, Neoplatonism and the occult, all within a Christian framework. His works, usually in German rather than Latin, were mostly published after his death. His importance for medical practice lay in his insistence on observation and experiment, and his use of chemical methods for preparing drugs. He rejected Galen's explanation of disease as an imbalance of humours, along with the traditional doctrine of the four elements. He saw the human being as a microcosm that reflected the structure and elements of the macrocosm, thus presenting a unified view of human beings and a universe in which everything was interconnected and full of vital powers. Paracelsian chemical medicine was very popular in the late sixteenth and seventeenth centuries, largely due to its presentation as part of a general theory.

1 Life and works

Theophrastus Bombastus von Hohenheim (sometimes given the additional names Philippus Aureolus) was born in Einsiedeln, a small Swiss town near Zürich. His pseudonym, Paracelsus, first recorded in 1529, may mean 'greater than Celsus' (a Roman medical writer). When his father, a medical doctor interested in alchemy, moved to Villach in Austria in 1502, Paracelsus came into contact with mining technology and the study of metals. He worked as an apprentice in the mines near Schwaz, but otherwise little is known of his education. He may have studied with Johannes Trithemius (1462-1516), author of many works on magic. He probably studied medicine at the University of Ferrara (1513-16), though there is no documentary evidence that he received a degree. Although medical training had a practical component, the focus was academic, involving study of standard Latin translations of Hippocrates (see Hippocratic medicine), Galen and Avicenna (see Galen; Ibn Sina). He then worked as an army surgeon during his travels across Europe from 1517 to 1524. Surgery was primarily a practical discipline, and much of the surgical literature was in the vernacular. The relationship between academically trained physicians and surgeons was an uneasy one, and Paracelsus persistently complained that he was recognized as a surgeon, not as a physician. From 1524 to 1525 Paracelsus was in Salzburg, but had to leave in a hurry, possibly because of involvement in a peasant rebellion. Subsequently he visited a number of spas, and developed an interest in the minerals found in spa waters. In 1526 he was in Strasbourg where he made some useful contacts leading to his appointment (March 1527) as municipal physician in Basle. This post carried with it the right to lecture, and led to a major clash with the university, which had not been consulted. Paracelsus announced that he was not going to teach the works of Hippocrates and Galen, and he burned the Canon of Avicenna in public. Furthermore, he gave his lectures in Swiss-German, not Latin. After verbally attacking a magistrate for not giving him full support in a case he brought for non-payment of fees (a frequent problem), he was forced to flee from Basle early in 1528. He now began a second set of journeys in Switzerland, Austria, Bohemia and Southern Germany, which are much better documented than his earlier journeys. In 1529, he visited Nuremberg where he studied and wrote on syphilis. He gave a very accurate description of the disease, but his recommendations for treatment were highly controversial. In 1533 he spent time in the mining areas of Appenzell, studying the diseases of miners, and giving the first written account of an occupational disease. He also continued his studies of spa waters. He claimed that he effected many marvellous medical cures, but seems never to have had much financial success. He was invited to Salzburg by the bishop, but died there in 1541, leaving few possessions.

Paracelsus was a prolific writer, though few of his works were published during his lifetime. Those that were, tended to be about prophecy and astrological forecasts. A few works require special mention. In his *Paragranum* (1529-30), he argued that medicine should be based on the four pillars of natural philosophy, astronomy, alchemy and virtue, by which he meant the individual powers of doctors, patients, herbs and metals. In his *Volumen medicinae paramirum* (*c.*1520) and his *Opus paramirum* (1531) he discussed basic medical doctrines. His main work on surgery, *Grosse Wundarznei*, was written in 1536 and printed immediately. His greatest and most comprehensive work, *Astronomia Magna*, was written 1537-8 and published in 1571. The first collected edition of his works dates from 1589-91, and was followed by other editions and by Latin translations. His works were widely diffused during the seventeenth century.

2 Microcosm and macrocosm

Paracelsus attacked medical orthodoxy in the name of Christian philosophy. He set out to find a new basis for medicine, and indeed for the study of the whole human being, by reverting to the ancient wisdom of Neoplatonism, enriched by elements from Hermeticism (or Hermetism), alchemy, astrology and magic. His favourite contemporary source was Marsilio Ficino (§2). He presented the resulting mixture in a biblical framework, emphasizing the necessity of Christian faith for those who sought the power of controlling natural forces, especially in healing the sick. He also emphasized the old doctrine of the two Books, the Book of Nature and the Book of Revelation (namely, the Bible), from both of which humans must learn to read.

Paracelsus' central doctrine concerned the relationship between the greater world, the macrocosm, and the lesser world, the microcosm, or human being. The elements making up the human being are those found in the macrocosm, and their structural relations are the same. In particular, the human reflects physical reality through the corporeal body which is perishable, living or spiritual reality through the astral body which gives life but is also perishable, and purely spiritual reality through the immortal soul which will take on an eternal body. Conversely, just as the human being is alive, so the macrocosm is permeated by life, and even metals grow. Furthermore, the entire universe is characterized by an elaborate series of correspondences. Plants and minerals contain powers or virtues which capture those of celestial bodies, and these powers in turn relate to states of the human body.

These doctrines have both epistemological and practical implications. Because the human being reflects the macrocosm, knowledge of external objects can be reached through knowledge of internal states and relations, particularly those involving the astral body. Knowledge is also bound up with power. Although human beings are endowed with wisdom, and hence are not governed by the stars, knowledge of the stars is particularly important in practice. Astrology enables us to know the powers, relations and influences of celestial bodies, and natural magic shows us how to control them.

Paracelsus' natural philosophy included a new doctrine of elements. He rejected the traditional four elements of earth, air, fire and water, accepting them only as visible composites. In their place he proposed sulphur and mercury, both found in Arabic alchemical sources, and salt, which he added himself. These elements should not be confused with the composites we normally call sulphur, salt and mercury. As an element, sulphur represents a principle of organization, mercury a principle of activity, and salt a principle directing matter towards a solid state. Nor should they be thought of as basic particles, for they have different qualities in different objects.

3 Medicine and chemistry

Paracelsus' rejection of the traditional four elements had a direct effect on his medical theory. Traditional medicine explained illness in terms of the four humours or bodily fluids to which the four elements gave rise: blood, phlegm, choler (or red or yellow bile) and black bile (or melancholy). Illness was taken to be a lack of balance between the four humours, a balance restored through diet and herbal medicine. Emotions, too, were linked to the four humours, and people were sanguine, phlegmatic, choleric or melancholic according to which humour predominated. These internal, mechanistic explanations were dismissed by Paracelsus. For him, diseases are distinct from one another, and are often related to chemical imbalances in specific organs that result from an interaction with external agents. These agents could be minerals, or they could be 'astral poisons' transmitted by the air. Astral influences were particularly important in explaining mental illness. Diseases are combated through the plants and metals whose 'signatures' show them to have the appropriate virtues or powers. There is always a precise correspondence between a disease and its antidote (see Medicine, philosophy of; Hippocratic medicine).

Paracelsus brought his practical experience to bear on the problem of treating diseases. Through his studies of alchemy and mining he had learned much about metals, and metallurgical techniques. He developed new laboratory methods, such as the concentration of alcohol by freezing. He used chemical techniques to derive extracts from traditional herbs, but more importantly he employed such substances as mercury, arsenic and antinomy in his treatments. Unfortunately, while his observations of diseases were remarkably exact, it is unlikely that his ability to cure them surpassed that of traditional practitioners.

Paracelsus' real achievement was his unified approach to chemistry which brought together alchemical, metallurgical and pharmaceutical techniques. Indeed, he came to see the whole world and its creation in terms of chemical transformation and separation.

4 Influence

From the 1550s onwards, as his works were edited and translated, Paracelsus' reputation began to grow. Paracelsian doctors were appointed to various European courts. Van Helmont was influenced by him, and Newton possessed a major edition of his works. At the same time, his philosophy was attacked by such figures as Mersenne and Gassendi, and there were disputes, often complex and bitter, between Galenists and Paracelsians in faculties of medicine.

Paracelsianism is particularly significant for the history of modern science. In the words of Charles Webster, 'the first major confrontation of the Scientific Revolution was between Paracelsus and Galen, rather than between Copernicus and Ptolemy' (1982: 3-4). The reasons for Paracelsus' popularity had to do with his presentation of a mystical, vitalistic philosophy of nature within a Christian framework. The continued attention paid to Paracelsus, and to Neoplatonism and the occult in general, show that a non-mechanistic, non-quantitative, non-mathematical approach still made sense, even to those who, like Newton, were responsible for advances in the new science.

List of works

Paracelsus (*c*.1520-1541a) *The hermetic and alchemical writings of Aureolus Philippus Theophrastus Bombast*, trans. A.E. Waite, London: J. Elliott, 1894; repr. Berkeley, CA: Shambhala and New York: Random House, 1976.(Good translations of selected works on alchemy and hermetic medicine.)

Paracelsus (*c*.1520-1541b) *Sämtliche Werke. I. Abteilung. Medizinische, naturwissenschaftliche und philosophische Schriften (Collected Works. Division I: Writings on Medicine, Natural Science and Philosophy)*, ed. K. Sudhoff, vols 6-9, Munich: O.W. Barth; vols 1-5, 10-14, Munich and Berlin: R. Oldenburg, 1922-33.(Standard critical edition.)

Paracelsus (*c*.1520-1541c) *Sämtliche Werke. II. Abteilung. Die theologischen und religionswissenschaftlichen Schriften (Collected Works. Division II: Writings on Theology and Religion)*, vol. 1, ed. W. Matthiessen, Munich: O.W. Barth, 1923; vols 2-7 and supplementary volume, ed. K. Goldammer *et al.*, Wiesbaden: Franz Steiner, 1955-73.(Standard critical edition.)

Paracelsus (*c*.1520) *Volumen medicinae paramirum*, trans. K.F. Leidecker, *Bulletin of the History of Medicine*, supplementary vol. 11, Baltimore, MD: Johns Hopkins University Press, 1949.(Discussion of basic medical doctrines. The original text is found in *Sämtliche Werke. I. Abteilung*, vol. 1.)

Paracelsus (1529-30) *Paragranum*, in K. Sudhoff (ed.) *Sämtliche Werke. I. Abteilung. Medizinische, naturwissenschaftliche und philosophische Schriften*, vol. 8, Munich: O.W. Barth, 1922-33.(Argues that medicine should be based on the individual powers of doctors, patients, herbs and metals.)

Paracelsus (1531) *Opus paramirum*, in K. Sudhoff (ed.) *Sämtliche Werke. I. Abteilung. Medizinische, naturwissenschaftliche und philosophische Schriften*, vol. 9, Munich: O.W. Barth, 1922-33.(Discussion of basic medical doctrines.)

Paracelsus (1536) *Grosse Wundarznei*, in K. Sudhoff (ed.) *Sämtliche Werke. I. Abteilung. Medizinische, naturwissenschaftliche und philosophische Schriften*, vol. 10, Munich and Berlin: R. Oldenburg, 1922-33.(Paracelsus' major work on surgery.)

Paracelsus (1571) *Astronomia Magna*, in K. Sudhoff (ed.) *Sämtliche Werke. I. Abteilung. Medizinische, naturwissenschaftliche und philosophische Schriften*, vol. 12, Munich and Berlin: R. Oldenburg, 1922-33.(Paracelsus' most comprehensive work. Although written in 1537-8, *Astronomia Magna* was only published posthumously.)

Paracelsus (1951) *Selected Writings*, ed. J. Jacobi, trans. N. Guterman, New York: Pantheon; 2nd edn, 1958.(A thematically organized series of translations based on the critical edition; useful glossary and bibliography.)

Paraconsistent logic

A logic is paraconsistent if it does not validate the principle that from a pair of contradictory sentences, A *and* $\sim A$*, everything follows, as most orthodox logics do. If a theory has a paraconsistent underlying logic, it may be inconsistent without being trivial (that is, entailing everything). Sustained work in formal paraconsistent logics started in the early 1960s. A major motivating thought was that there are important naturally occurring inconsistent but non-trivial theories. Some logicians have gone further and claimed that some of these theories may be true. By the mid-1970s, details of the semantics and proof-theories of many paraconsistent logics were well understood. More recent research has focused on the applications of these logics and on their philosophical underpinnings and implications.*

The idea that a contradiction implies everything (*ex contradictione quodlibet* - ECQ) has always been a contentious one in logic. Despite this, formal paraconsistent logics, which do not validate ECQ, are creatures of the twentieth century. The earliest ones were constructed in Russia by N.A. Vasil'ev *c*.1912 - an Aristotelian logic - and I.E. Orlov in 1929 - a relevance logic (see Anderson, Belnap and Dunn 1992). However, these had no impact at the time.

Work on formal paraconsistent logics did not begin in earnest until after the Second World War. Since then they have been proposed independently by many logicians, the earliest notable ones being S. Jaśkowski (in Poland) in 1948, F.G. Asenjo (Argentina) *c*.1954, N.C.A. da Costa (Brazil) *c*.1958 and T.J. Smiley(the UK) in 1959. Work on relevance logic by A.R. Anderson and N.D. Belnap (in the USA) also started in the late 1950s (see Relevance logic and entailment), and the specifically paraconsistent aspects of relevance logic were developed by R. Routley and others (in Australia) in the late 1960s and 1970s. (Note that a paraconsistent logic need not be relevant.) Since then, work on formal paraconsistent logic has continued apace in many places, but most notably in Brazil (under the leadership of da Costa) and Australia. (Some of the original work is rather difficult to come by or of a rather preliminary nature. The best access points in the literature are: Jaśkowski (1969); Asenjo (1966); da Costa (1974); Anderson and Belnap (1975); and Routley (1977).)

A major motivation behind the construction of formal paraconsistent logics has always been the idea that in many contexts we may have information that is inconsistent, but from which we want to draw conclusions in a controlled way. (The term 'paraconsistent' was coined by M. Quesada at the third Latin American Symposium on Mathematical Logic in 1976, to indicate just this.) Examples that are frequently appealed to are: evidence provided by different witnesses, constitutions and other legal documents, various scientific theories, numerous philosophical theories, and information in a computer database. In such contexts, even though the data are incorrect, if we are stuck with them (as we may well be), then the logic had better be paraconsistent. Moreover, inconsistent scientific theories, even if they are not correct, may still be useful, or good approximations to the truth.

Some paraconsistent logicians have claimed that inconsistent theories may actually be true (see, for example, Priest 1987). The view that some contradictions or contradictory theories are true is called 'dialeth(e)ism' - from 'dialetheia' (a term coined by Priest and Routley in 1982), which means a true statement of the form $A \,\&\, \sim A$. The most commonly cited examples of dialetheias are the paradoxes of self-reference, such as Russell's and the liar paradox (see Paradoxes of set and property; Semantic paradoxes and theories of truth). The failure to obtain consensus on any consistent account of the paradoxes gives this suggestion its appeal. Other suggested examples of dialetheias include: statements about objects on the borderline of some vague predicate; moral dilemmas; and dialectical contradictions in the tradition of Hegel and Marx.

Some approaches to paraconsistent logic, such as Smiley's, obtain a suitable inference relation by starting with the classical one and filtering out ECQ and other undesirables. Such logics typically give up the transitivity of entailment. A more common approach is to specify a notion of entailment semantically, defined in terms of truth-preservation over a class of interpretations. For this approach, it is necessary to have a mechanism whereby contradictory sentences may simultaneously hold in an interpretation. For this reason, one may think of paraconsistent logic as a kind of dual of intuitionist logic (see Intuitionism), the former violating the law of non-contradiction, the latter violating the law of the excluded middle. (Though it is quite possible to have a paraconsistent logic in which $\sim (A \,\&\, \sim A)$ is semantically valid.) Paraconsistent logics of this kind

characteristically invalidate the Disjunctive Syllogism (DS): $A \vee B$ and $\sim A$ entail *B*. For both premises may be true in virtue of the properties of *A*, while *B* is not.

Various techniques have been proposed to achieve the required end. Jaśkowski's is to interpret 'true' as 'true in some possible world or other'. Da Costa's is to give up the truth-functionality of negation, so that if *A* is true, $\sim A$ may be either true or false. Routley's is to treat negation as an intensional operator, so that $\sim A$ is true at a world *w* if *A* is false at some associated world, w^*. Asenjo's suggestion (which can also be harnessed in the semantics of relevance logics) is to allow sentences to take a non-classical truth value, which may be thought of as *both true and false*, and which is a fixed point for negation.

By the mid-1970s the semantics and proof theories of many paraconsistent logics were well developed. More recently, much work has gone into their applications, both technical and philosophical. The technical applications all involve the investigation of inconsistent theories. Notable results in this area include a proof that naïve set theory with (an unrestricted comprehension axiom and) a suitable underlying paraconsistent logic is non-trivial (Brady 1989), and a proof (by R. Meyer) that there is a (consistent!) arithmetic that can prove its own non-triviality. The techniques involved in the latter involve the construction of models of full first-order arithmetic, many of which are finite (see Meyer and Mortensen 1984). It is also possible to construct non-trivial theories that contain both self-reference and epistemic operators, and that are semantically closed, in the sense of Tarski (see Priest 1991a).

The philosophical applications are more diffuse. Traditionally, consistency was thought to be the cornerstone of many important philosophical notions (for example, truth, rationality), but the viability of paraconsistent logic throws down a challenge to any such claim. In the light of this, a reappraisal both of such notions and of the significance of results that turn on consistency, for example, Gödel's incompleteness theorems, is called for and is in train.

Many would be prepared to concede the possibility of a limited use for paraconsistent logic, for example, as an inference engine for a computational database. The major criticism as far as this goes is that a paraconsistent logic is too weak to permit useful inference. In particular, a number of writers have argued that the DS is essential to most practical inference. In the author's opinion, this sort of objection carries little weight. For a start, the logical resources of the programming language PROLOG are validated in most paraconsistent logics when suitably interpreted. More generally, most paraconsistent logicians have been prepared to accept the usability of principles such as the DS in consistent ('normal'?) contexts. This idea has motivated the construction of formal non-monotonic logics in which the DS is a default inference (see Batens 1989; Priest 1991b).

Much of the criticism of paraconsistent logic has fallen on dialetheism. One of the chief general criticisms is that the paraconsistent semantics for negation fails to capture (true) negation, but this is difficult to make stick for the many-valued semantics. Some have argued that if contradictions are not to be rejected as logically unacceptable then logic is ruined as an instrument of rational criticism, but this objection trades on a confusion of what is possible according to formal logic and what is rationally possible. A third important general criticism is that if one is to accept *A* one must rationally reject $\sim A$. However, dialetheism aside, there are situations where we seem to have little rational option but to accept a contradiction (for example, the paradox of the preface). Most of the application-specific criticisms have tried to undercut a dialetheic solution to the self-referential paradoxes by arguing that paraconsistent solutions to these collapse into triviality - or, at least, fail to do so only by *ad hoc* manoeuvres of a kind that make consistent purported solutions so unsatisfactory. To date, such arguments have not hit the mark squarely. (On much of the above, see Smiley and Priest (1993).)

The possibility of violations of the law of non-contradiction was widely canvassed by pre-Aristotelian philosophers. Aristotle attacked this possibility in *Metaphysics* (1005b8-1009a5). His arguments are distinctly dubious, as was shown by Łukasiewicz (1971), but his authority has determined subsequent orthodoxy. Only a few (notably Hegel) have challenged it. Even fewer have produced a sustained defence of the law. The technical viability of paraconsistent logic and dialetheism therefore raises a challenge to contemporary philosophy of no little significance.

Paradoxes of set and property

Emerging around 1900, the paradoxes of set and property have greatly influenced logic and generated a vast literature. A distinction due to Ramsey in 1926 separates them into two categories: the logical paradoxes and the semantic paradoxes. The logical paradoxes use notions such as set or cardinal number, while the semantic paradoxes employ semantic concepts such as truth or definability. Both often involve self-reference.

The best known logical paradox is Russell's paradox concerning the set S of all sets x such that x is not a member of x. Russell's paradox asks: is S a member of itself? A moment's reflection shows that S is a member of itself if and only if S is not a member of itself - a contradiction.

Russell found this paradox by analysing the paradox of the largest cardinal. The set U of all sets has the largest cardinal number, since every set is a subset of U. But there is a cardinal number greater than that of any given set M, namely the cardinal of the power set, or set of all subsets, of M. Thus the cardinal of the power set of U is greater than that of U, a contradiction. (The paradox of the largest ordinal, discussed below, is similar in structure.)

Among the semantic paradoxes, the best known is the liar paradox, found by the ancient Greeks. A man says that he is lying. Is what he says true or false? Again, either conclusion leads to its opposite. Although this paradox was debated in medieval Europe, its modern interest stems from Russell, who placed it in the context of a whole series of paradoxes, including his own.

1 General comments

Etymologically, a paradox is something 'against' ('para') '[common] opinion' ('dox'). Nowadays it means a claim that seems absurd but has an argument to sustain it. A paradox appears 'paradoxical' when one is uncertain which premise to abandon.

The paradoxes about sets involve the principle of comprehension, which states that, for any concept, there is a class of all those objects for which the concept is true. (We use the terms 'class' and 'set' interchangeably, thus allowing each author discussed below to keep his own terminology.) Historically, the paradoxes about sets are related to the traditional antinomies of the infinite (as expressed, for example, by Galileo), to Zeno's paradoxes and to Kant's antinomies (see §4 below).

2 Burali-Forti: how not to discover a paradox

The paradox of the largest ordinal, often called Burali-Forti's paradox, is as follows. The set of all ordinals is well-ordered and so has an ordinal number, Ω, which is the largest ordinal. But for any ordinal α, there is a larger ordinal $\alpha + 1$. Hence $\Omega + 1$ is larger than Ω, a contradiction.

The early history of this paradox is a comedy of errors. In 1897 Cesare Burali-Forti *almost* discovered it. He failed to do so because he misunderstood Cantor's definition that a linearly ordered set is 'well-ordered' if (a) it contains a first element, (b) every element with a successor has an immediate successor and (c) every set of elements with a successor has an immediate successor. Accidentally omitting (c) from the definition, Burali-Forti introduced a new notion of 'perfectly ordered class' and gave for such classes an argument close to the paradox. But the conclusion he drew was that the order types of such classes are not linearly ordered. He did not think he had discovered a paradox, since nothing that he wrote challenged previous results. Later that year, he realized that he had misconstrued Cantor's definition, but saw no contradiction between his work and Cantor's, since his concerned perfectly ordered classes, not ordinals. For five years, there was no discussion in print about Burali-Forti's article. (This has often been mistakenly denied, as when van Heijenoort stated that Burali-Forti's article 'immediately aroused the interest of the mathematical world' (1967: 104).)

In 1902, after Louis Couturat alerted him to Burali-Forti's work, Russell asserted (wrongly) in print that Burali-Forti claimed that the ordinals are not linearly ordered. Here was the beginning of a genuine paradox, for Russell applied Burali-Forti's argument to the ordinals. Russell's solution was to claim that the class of all ordinals has no ordinal since it is not well-ordered. (Later he rejected this solution.)

In 1903 Russell gave the first clear statement of the paradox of the largest ordinal in his book *The Principles of Mathematics*. Thus Russell was the key figure in its emergence. Alonzo Church erroneously claimed that ‘it was through Burali-Forti’s paper that there first came to general attention the threat to the foundations of mathematics that is constituted by the antinomies’ (1971: 235). It was not Burali-Forti but Russell who first pointed out this threat in print.

3 Cantor: side-stepping the paradoxes

In 1883 Cantor had introduced infinite ordinal numbers (see Set theory; Cantor’s theorem). He distinguished sharply between finite ordinals, infinite ordinals and what he called the ‘absolutely infinite’, which included the set of all ordinals. In 1897, when Hilbert asked whether every set can be well-ordered, Cantor answered yes. Cantor’s argument indirectly included the paradox of the largest ordinal and explicitly relied on the absolutely infinite. Yet he did not regard this as paradoxical, since he had previously made the relevant distinction between the infinite and the absolutely infinite. (E.H. Moore independently found this ordinal paradox and wrote about it to Cantor in an unpublished letter of 1898.)

Replying to Hilbert, Cantor made the notion of the absolutely infinite more precise. In print two years earlier, he had defined a set as a ‘gathering together’ of distinct objects. Now he called a set ‘completed’ if it is possible, without contradiction, to think of all its members as gathered together into a whole; any other set, such as that of all ordinals, was ‘absolutely infinite’. In his Paris lecture of 1900, Hilbert affirmed that each of Cantor’s infinite cardinal numbers is consistent, but denied that there exists a set of all cardinals. Nevertheless, Hilbert gave no indication that set theory was threatened.

In 1899 Cantor communicated to Dedekind the proof that every set can be well-ordered (see Cantor 1991). Once more, the paradox of the largest ordinal was involved when Cantor showed, as part of the proof, that the collection of all ordinals is absolutely infinite. Now Cantor distinguished between what he called consistent collections and inconsistent collections; only the former were sets. (A ‘consistent’ collection was what he had earlier called ‘completed’.) Writing to Hilbert shortly afterwards, Cantor saw Dedekind’s foundation as threatened, since Dedekind assumed that every well-defined collection was consistent. Cantor had pointed out to Dedekind that the collection of everything thinkable, which Dedekind had used to prove the existence of an infinite set, was inconsistent.

4 Russell: the paradoxes emerge

The paradoxes were not discussed in print until 1903, when they appeared in Russell’s *Principles of Mathematics*. But Russell had found the paradox of the largest cardinal before he learned of Burali-Forti’s article or of Cantor’s unpublished thoughts on the subject. Russell’s own paradox emerged in May 1901 from simplifying his paradox of the largest cardinal.

But the roots of Russell’s paradox go much deeper. In 1896 he had rejected Cantor’s infinite ordinals as ‘impossible and self-contradictory’. During that period Russell proposed various antinomies in the spirit of Kant and Hegel, including the ‘contradiction of relativity’. In 1898 he characterized mathematics as follows:

> One pervading contradiction occurs almost… universally. This is the contradiction of a difference between two terms, without a difference in the conceptions applicable to them. I shall call it the contradiction of relativity. This, with addition and the manifold, appear to define the realm of Mathematics.
>
> (1898: 166)

By 1899, Russell was no longer an idealist but a Platonist. Although he ceased propounding antinomies in the style of Kant, he proposed one that originated with Leibniz. ‘Mathematical ideas’, he wrote in his 1899-1900 draft of the *Principles*, ‘are almost all infected with one great contradiction. This is the contradiction of infinity. All antinomies,… so far as they are valid at all, will be found reducible to the antinomy of infinite number’ (1900: 70).

What was this antinomy of infinite number? In 1899 Russell gave it the following form, while distinguishing between

> (a) all numbers, (b) the greatest number, (c) the last number. Observe that (b)… means the number applying to the greatest collection. All three are commonly called infinite number, and imply an antinomy, since their being

> can be both proved and disproved. (a) the most fundamental: There are many numbers, therefore there is a number of numbers. If this be *N*, $N + 1$ is also a number, therefore there is no number of numbers.
>
> (1899: 265)

Russell's antinomy of infinite number has the same formal structure as the paradox of the largest cardinal, which he formulated only in late 1900. That paradox can be stated in the following way: the class of all cardinal numbers has a cardinal number; but there is another class which has a larger cardinal number (by Cantor's theorem, the set of subsets of a set with cardinal *N* has a cardinal larger than *N*); hence there is no cardinal number of the class of all cardinal numbers. Likewise, the antinomy of infinite number has the same formal structure as his later paradox of the largest ordinal.

In November 1900 Russell redrafted part of the *Principles*. The following passage from that draft manuscript contains the earliest version of his paradox of the largest cardinal, which is closely connected with the antinomy of infinite number.

> There is a certain difficulty in regard to the number of numbers, or the number of individuals or of classes. Numbers, individuals, and classes, each form a perfectly definite class, and… every class must have a number. Now the number of individuals must be the absolute maximum of numbers, since every other class is a proper part of this one…. But Cantor has given two proofs… that there is no greatest number.

Soon Russell informed Couturat that Cantor's proofs were erroneous when applied to the class of all classes. Couturat doubted the existence of that class. But Russell vigorously defended it: 'If you grant that there is a contradiction in this concept, then the infinite always remains contradictory' (Moore and Garciadiego 1981: 327).

In May 1901 Russell discovered his paradox by applying Cantor's proof that there is no greatest cardinal to the class of all classes. During that month he wrote the earliest surviving manuscript containing his paradox. It was not expressed in terms of classes but of predicates:

> We saw that some predicates can be predicated of themselves. Consider now those… of which this is not the case…. But there is no predicate which attaches to all of them and to no other terms. For this predicate will either be predicable or not predicable of itself.
>
> (1993: 195)

Either case implies the opposite, hence a contradiction. Thus there is no predicate predicable of all and only those predicates not predicable of themselves. Russell concluded that the principle of comprehension was false. A year later, he wrote to Frege about it. While Frege saw that the paradox for predicates did not arise in his system, he was devastated by the class form of Russell's paradox. Frege abandoned the principle of comprehension, which seemed to him the only possible logical foundation for arithmetic.

In 1903 Russell published Russell's paradox, together with the paradoxes of the largest cardinal and the largest ordinal, in the *Principles*. By that date, one or more of these three paradoxes was also known to Dedekind and Hilbert (thanks to Cantor), to Husserl (thanks to Zermelo; see §5 below), to Peano (thanks to Russell) and to E.H. Moore (independently, in a letter to Cantor), but none of them published such a result. Russell's and Frege's reactions to the paradoxes, which they treated as a major challenge, stand in striking contrast to the early reactions of the others mentioned.

Russell's book also generalized his paradox: if *R* is a relation, suppose there is some *w* such that, for any *x*, *x* has the relation *R* to *w* if and only if *x* does not have the relation *R* to *x*; substituting *w* for *x* leads to a contradiction; hence there is no such *w* (1903: 102). (Russell's paradox results from substituting membership for *R*.) Later Quine expressed Russell's generalization as follows: nothing can have a relation to all and only those things that do not have it to themselves.

At the end of this book Russell tentatively presented his earliest version of the theory of types as a solution to the paradoxes. Then '*x* is a member of *x*' was meaningless, since if *x* is a member of *u*, then *x* and *u* had to belong to different types (see §7 below).

5 Hilbert, Bernstein and Grelling: German reaction to the paradoxes

Cantor was not alone in recognizing, before paradoxes were published, that there is no set of all sets. In his 1890 book on the algebra of logic, Ernst Schröder rejected such a universal set, arguing that it leads to a contradiction. Reviewing Schröder's book, Edmund Husserl rejected both Schröder's argument and his conclusion, since both resulted from a failure to distinguish between being a member of a set and being a subset. In 1902 Ernst Zermelo informed Husserl that Schröder was correct in his conclusion, although mistaken in his argument. Zermelo showed that a set which contains each of its subsets as a member is self-contradictory. He did so by stating Russell's paradox, which he had found by 1900, before Russell. Zermelo concluded that there is no set of all sets.

In 1903 Hilbert wrote to Frege that Zermelo had discovered Russell's paradox three years earlier, after Hilbert had informed Zermelo of other paradoxes which Hilbert had found a year before that. (In an 1899 letter to Frege, Hilbert had observed that there is no set of all cardinal numbers, but gave no hint that this was a threatening discovery.) Influenced by Frege rather than Russell, Hilbert first published on the paradoxes in 1905. He rejected the principle of comprehension, regarding it as the source of the paradoxes. These showed that traditional logic did not satisfy the demands of set theory; they would be solved only by an axiomatic development of logic. That year he devoted a long series of lectures to the problem without coming to a solution. Although one often reads that he did not concern himself with logic during the next decade, in fact he repeatedly lectured on the paradoxes. He only reached a solution in 1917 when he adopted Russell's theory of types (see §7 below).

In Germany the first published discussion about the paradox of the largest ordinal occurred in 1905. Felix Bernstein used this paradox while attempting to refute Zermelo's proof (1904) that every set can be well-ordered, arguing that there is indeed a set *W* of all ordinals (Moore 1982: chap. 2). But in France, Jacques Hadamard rejected Bernstein's argument: 'It is the very existence of the set *W* that generates a contradiction…. One has the right to form a set only with previously existing objects, and it is easily seen that the definition of *W* presupposes the opposite' (Hadamard in Moore and Garciadiego 1981: 339).

Several neo-Friesian philosophers commented on the paradoxes, including Alexander Rüstow (1910), in his book on the liar paradox, and Gerhard Hessenberg (1906), who found the notion of set unclear. Hessenberg argued that Russell's paradox was not dangerous for mathematicians, since they did not use a universal set, but that the paradox of the largest ordinal was dangerous.

In 1908 the neo-Friesian philosophers Kurt Grelling and Leonard Nelson discussed those paradoxes, including the predicate form of Russell's paradox. Grelling formulated a related paradox, later called Grelling's paradox: a word is called autological if it applies to itself, and otherwise is called heterological. Thus 'short' is autological and 'long' is heterological. Now 'heterological' is either autological or heterological. But either possibility leads to the opposite.

6 Berry, König and Richard: paradoxes of definability

The first paradoxes of definability emerged during 1904-5 from three distinct sources. Richard's paradox, due to Jules Richard, was the first to be published. Conceived as a response to Hadamard's comments on the paradox of the largest ordinal (see §5 above), but directed at the continuum of real numbers, Richard's paradox was the following: consider in decimal form all the real numbers that can be defined by a finite number of words. These numbers form a denumerable set *E*, whose members are $a_1, a_2, a_3, \ldots$. We define a real number *N* not in *E* by letting the *n*th decimal place of *N* be one more than the *n*th place of a_n unless the *n*th place is 8 or 9 (in which case the *n*th place of *N* is 1). Since *N* differs from the *n*th place of a_n for each *n*, then *N* is not in *E*. But *N* is defined by a finite number of words and so is in *E*, a contradiction.

In 1906 Henri Poincaré stressed the importance of Richard's paradox, and found in it a single explanation for all the paradoxes: objects defined by a vicious circle must be avoided. In Richard's paradox, there is a vicious circle since *N* is defined by using *E* but is itself in *E*. If one restricted *E* to those numbers defined without reference to *E*, there would be no contradiction. Yet Poincaré viewed the actual infinite, which he rejected, as being equally the source of the paradoxes.

Although it was the first definability paradox to be published, Richard's was not the first to be discovered. That honour goes to George Berry of Oxford University. In December 1904 Berry sent Russell the following paradox: consider the least ordinal not definable in a finite number of words; this ordinal is itself defined in a finite number of words, a contradiction.

This paradox, which Russell published in 1906 in response to Poincaré's comments on Richard's paradox, is known by the name he gave it: the paradox of the least indefinable ordinal. At that time Russell modified this paradox to give one that did not involve the actual infinite and that he called Berry's paradox, although Berry did not formulate it: the least integer not nameable in fewer than nineteen syllables. But this integer has just been named in eighteen syllables, a contradiction.

A fourth paradox of definability, called the Zermelo-König paradox, was found in 1905 by Julius König, who published it not as a paradox but to refute Zermelo's claim that the continuum of real numbers can be well-ordered. König observed that the set of real numbers which are definable in a finite number of words is denumerable. Since the continuum is not denumerable, there are real numbers *x* which cannot be defined in a finite number of words. If the continuum can be well-ordered, then there is a least such *x*, a contradiction. Hence the continuum cannot be well-ordered.

Once Richard's paradox was seen to be similar to König's result, it became clear that they concerned definability and had nothing to do with well-ordering the continuum.

7 Russell: solving the paradoxes by type theory

In 1905 Russell discussed three kinds of solutions to the paradoxes: zigzag theories, theories of limitation of size, and no-classes theories. In a zigzag theory, a property $\phi(x)$ determines the class of all *x* satisfying $\phi(x)$ when $\phi(x)$ is sufficiently simple; the difficulty with such a theory, Russell noted, was in specifying what made $\phi(x)$ sufficiently simple. A theory of limitation of size, such as that of Cantor or later Zermelo, would state that a property $\phi(x)$ determines the class of all *x* satisfying $\phi(x)$ if the class is 'limited' in size; the difficulty here was to specify how large an ordinal exists. Finally, a no-classes theory would dispense with assuming the existence of classes and operate directly with properties; although such a theory would preserve classical analysis and geometry, it was unclear how much set theory would survive.

Russell also gave a general form to all paradoxes about classes: suppose that there is a property ϕ and a function *f* such that if ϕ is satisfied by all members of the class *u*, then $f(u)$ satisfies ϕ and is not a member of *u*; the assumption that there is a class *w* of all *x* satisfying ϕ and that $f(w)$ exists leads to the contradiction that $f(w)$ has and does not have the property ϕ. In Russell's paradox, ϕ is '*x* is not a member of *x*' and $f(u)$ is *u*; in the paradox of the largest ordinal, ϕ is '*x* is an ordinal' and $f(u)$ is the ordinal number of *u*.

In the *Principles* (1903) Russell had tentatively presented his earliest version of the theory of types as a solution to the paradoxes. But during 1903 Russell became dissatisfied with his theory of types, and in 1904 adopted a zigzag theory. In 1905 and 1906 he preferred a no-classes theory. But the boundaries between his different theories were fuzzy. In 1906 he stressed that his no-classes theory contained types and was close to his 1902 theory of types.

The emergence of definability paradoxes coincided with a shift in Russell's views. Earlier, he had primarily investigated paradoxes involving classes. In 1906 he was increasingly occupied with the liar paradox. In that context he formulated the vicious circle principle, which any proposed solution to the paradoxes must satisfy: whatever involves a bound variable must not be a possible value of that variable. While accepting Poincaré's analysis that vicious circles caused the paradoxes, Russell vigorously rejected Poincaré's claim that the actual infinite caused them too.

In 1908 Russell published his *ramified* theory of types, which included much of the no-classes theory. Whereas in 1900 Russell had vigorously defended the class of all classes, his theory of types explicitly rejected it (as well as the notions of all propositions, all relations, all definitions and all ordinals). The heart of the theory was the distinction between orders and types, where orders concerned definitions, and the central assumption was his dubious axiom of reducibility, which was used to solve the semantic paradoxes.

Russell's theory was not well received at first, and was rejected by Poincaré in part because of the axiom of reducibility. The *simple* theory of types, which dispensed with this axiom and with definability, was due to Leon Chwistek and Ramsey in the 1920s (see Theory of types). In the simple theory, there was no concern with the semantic paradoxes, which could not even be formulated in it.

8 Zermelo: solving the paradoxes by axiomatizing set theory

In 1908 Zermelo published his axioms for set theory, without reformulating logic or mentioning the semantic paradoxes. To understand Zermelo's motivation, we must consider two articles he published that year in the same journal, finished within two weeks of each other, and which referred to each other. The second article contained his axiomatization, while the first defended his theorem that every set can be well-ordered. The first also gave a new proof of his theorem, based explicitly on axioms from his second article. The two articles form a single unity, revealing that his axiomatization was motivated as much by a concern to secure his theorem as by the need to solve the paradoxes (see Moore 1978).

The key to Zermelo's axiomatization was his axiom of separation, which restricted the principle of comprehension to subsets of any previously existing set. To preserve set theory, he included axioms which generated sets from previously existing sets, especially the power set and union axioms (see Set theory, different systems of).

But Zermelo's approach seemed arbitrary until he introduced the cumulative type hierarchy of sets in 1930. This hierarchy began with the empty set as the lowest level, and any level *S* was followed by a next level, the power set of *S*. The levels were indexed by ordinals, and when the index was a limit ordinal, the level was the union of all previous levels. The hierarchy of levels was cumulative since a member of any level belonged to all following levels, by contrast with Russell's types, which were disjoint.

Today Zermelo's hierarchy, as embodied in the Zermelo-Fraenkel axioms formulated in first-order logic, is generally accepted by mathematicians as the proper solution to the logical paradoxes. Among philosophers, the semantic paradoxes still lack such a generally accepted solution.

9 Brouwer, Weyl and Skolem: attacking set theory with paradoxes

Opponents of set theory repeatedly used the paradoxes as a weapon against it. This began with Poincaré in 1906 and continued with Brouwer in 1907 (see Intuitionism). Both saw intuition as central, the axiomatization of logic as suspect, and the natural numbers as fundamental. Both engaged in later attacks on axiomatization and set theory. A decade later Hermann Weyl continued the attack on analysis and set theory, using Grelling's and Richard's paradoxes.

In 1923 Thoralf Skolem used a different paradox to argue that set-theoretic concepts are relative, not absolute. Skolem's paradox states that there is a countable model for axiomatic set theory, although there exist uncountable sets. The solution distinguishes between levels. There exists some set *M* which is uncountable within the model, where there is no function mapping *M* onto the natural numbers; but outside the model there is such a function, and so, from outside, all the sets in the model are seen as countable.

10 Zermelo, von Neumann and Gödel: turning paradoxes into theorems

From a mathematical perspective, what is most striking is how paradoxes have repeatedly been turned into theorems. We consider four examples.

For Zermelo, Russell's paradox became the theorem of his axiomatic set theory that there is no set of all sets (1908).

For von Neumann, the paradox of the largest ordinal became the theorem of his axiomatic set theory (1925) that every set can be well-ordered. The proof was based on the axiom that every proper class (and no set) can be mapped one-to-one onto the class of all sets. Thus proper classes, which were 'too big' to be sets, were rehabilitated by no longer being considered to be contradictory, as they had been for Cantor and Zermelo. In effect, von Neumann made precise Cantor's distinction between consistent and inconsistent collections.

Gödel's incompleteness theorem, which states that any sufficiently rich formal system contains propositions that cannot be proved or refuted in the system (see Gödel's theorems), was obtained, in part, by applying Richard's paradox to the notion of provability (1931).

Finally, Tarski's theorem on the indefinability of truth (1933) had a close connection with the liar paradox. Tarski saw the universality of natural languages as the source of the semantic paradoxes, since this universality allows truth to be defined in such languages (see Tarski's definition of truth).

Paradoxes, epistemic

The four primary epistemic paradoxes are the lottery, preface, knowability, and surprise examination paradoxes. The lottery paradox begins by imagining a fair lottery with a thousand tickets in it. Each ticket is so unlikely to win that we are justified in believing that it will lose. So we can infer that no ticket will win. Yet we know that some ticket will win. In the preface paradox, authors are justified in believing everything in their books. Some preface their book by claiming that, given human frailty, they are sure that errors remain. But then they justifiably believe both that everything in the book is true, and that something in it is false.

The knowability paradox results from accepting that some truths are not known, and that any truth is knowable. Since the first claim is a truth, it must be knowable. From these claims it follows that it is possible that there is some particular truth that is known to be true and known not to be true.

The final paradox concerns an announcement of a surprise test next week. A Friday test, since it can be predicted on Thursday evening, will not be a surprise yet, if the test cannot be on Friday, it cannot be on Thursday either. For if it has not been given by Wednesday night, and it cannot be a surprise on Friday, it will not be a surprise on Thursday. Similar reasoning rules out all other days of the week as well; hence, no surprise test can occur next week. On Wednesday, the teacher gives a test, and the students are taken completely by surprise.

1 Lottery and preface paradoxes

The lottery paradox - first developed in Kyburg (1961) - and the preface paradox - originally formulated in Makinson (1965) - have a similar structure, although some (for example, Pollock (1986)) hold that they have different solutions. Each hinges on a conflict between a rule of acceptance, a condition on the transfer of warrant, and an axiom about warrant.

Rule of acceptance: There is some threshold short of certainty where acceptance of a claim is warranted or justified.
Transfer condition: A set of warranted claims is closed under deduction. That is, a set of warranted claims includes all the deductive consequences of that set.
Warrant axiom: It is not possible to be warranted in believing *p* and, for the same time and the same individual, be warranted in believing not *p*.

One standard approach is to find some fault with the transfer condition. Denials of the transfer condition sometimes result from explicit consideration of these paradoxes, sometimes from more general considerations within the theory of knowledge. For example, Kyburg addresses the lottery paradox explicitly and holds that it relies on the faulty conjunction principle, the principle according to which a person is warranted in believing a conjunction *p&q* if they are warranted in believing *p* and warranted in believing *q*. In this way, outright contradictions are thought to be avoidable in the set of warranted beliefs for a person at a time, while still allowing that the set can be inconsistent, that is, be such as to deductively imply a contradiction. Other epistemologists (for example, Nozick (1981)) develop general theories of knowledge to answer the Gettier problem in which the transfer condition is abandoned (see Gettier problems; Deductive closure principle).

To accept such a solution may require abandoning a coherence theory of justification, for a commonly proposed minimal condition for coherence is logical consistency. If this approach is the best available for solving these paradoxes, the paradoxes will have taught us that coherence theories of justification must be abandoned (see Knowledge and justification, coherence theory of §3).

A point of importance concerning those who abandon the transfer condition explicitly to solve the paradoxes is that abandoning the conjunction principle alone will not do the trick: the paradoxes can be generated without employing any conjunction principle. In the lottery paradox, one can infer from individual premises that each particular ticket will lose, together with the knowledge of exactly how many tickets there are in the lottery, that no ticket will win. This claim can be deduced without using the conjunction principle, yet contradicts the knowledge that some ticket will win, thereby violating the warrant axiom according to which contradictory warranted claims are impossible.

Moreover, a fully satisfactory solution to these paradoxes that denies the deductive closure condition would need to offer an alternative principle in its place. For it is obvious that some of our beliefs are warranted precisely because we deduce them from other things we know.

A different approach is to question the rule of acceptance. There are two approaches that could be taken here. The first is simply to succumb to the paradox, granting that no acceptance is ever warranted when a claim is less than certain. This solution, however, seems unduly restrictive. For the small chance of illusion, hallucination and other types of misperception indicate that our ordinary perceptual beliefs are less than certain.

Alternatively, one may be suspicious of the idea of acceptance or belief, on Bayesian grounds. Bayesian epistemology arises within the context of an application of a subjective interpretation of probability theory to epistemological issues, and begins by noting that we believe some things more strongly than others (we believe that 2 + 2 = 4, and that there is at present no life on Mars, but we are much more confident of the first than the second) (see Probability theory and epistemology). So, perhaps, the concept of belief in ordinary language is a coarse-grained way of talking about certain mental states that, strictly speaking, only come in degrees. Once such a viewpoint is accepted, two lines emerge as to how to treat the ordinary concept of belief. First, one might hold that there is no such thing as belief *simpliciter*, but rather there are only *degrees of belief*, and hence that the acceptance condition is ill-formed since it is formulated using the concept of belief *simpliciter*. Another alternative is to think that there is some way of understanding the ordinary concept of belief in terms of degrees of belief, using the lottery and preface paradoxes to show that such a definition cannot proceed in terms of some threshold of degree of belief above which the ordinary concept of belief applies (Kaplan 1981). The task for this kind of Bayesian view is to give an account of the ordinary concept of belief which, in conjunction with the transfer condition, does not violate the warrant axiom. In either case, the Bayesian approach gives some reason to be suspicious of the acceptance condition, and thereby suggests that the paradoxes might best be dealt with by abandoning or altering that condition.

2 Knowability paradox

The knowability paradox derives from work by Fitch (1963) on value concepts. The paradox depends on two claims:

(1) Everything is knowable - that is, for all propositions *p*, if *p* is true, then it is possible that it is known (by someone at some time) that *p* is true.
(2) Some things are not known - that is, there exists some proposition *p*, such that *p* is true, and it is not known that *p* is true.

We then substitute an instance of (2) - a claim of the form '*q* is true and it is not known that *q* is true' - as the value for *p* in the first claim. Since we are committed to the truth of this instance of (2), the antecedent of (1) is true when this instance of (2) is the value for *p* in (1). We thus deduce that it is possible that a certain conjunction is known, namely that *q* is true and that it is not known that *q* is true. Since to know a conjunction is to know that each of its conjuncts is true, we can infer that it is possible that it is known that *q* is true and that it is known that it is not known that *q* is true. However, since knowledge implies truth, the latter piece of knowledge implies that it is not known that *q* is true. So we thereby deduce that it is possible that it is both known and not known that *q* is true.

The crucial features of this argument are the distribution principle (that is, that knowledge of a conjunction implies knowledge of each of the conjuncts) and the factive character of knowledge (that is, that knowing *p* implies *p*). The remainder of the argument relies on no principles of inference beyond those of first-order quantification theory with modal operators. So the paradox has much broader implications than merely those concerning knowledge. Fitch (1963), for example, used the paradox to argue that verificationism, the thesis that all truths are knowable, entails a very silly form of verificationism according to which all truths are known (see Meaning and verification §6). The broader implications of the paradox, almost completely unaddressed in the literature, concern versions of antirealism according to which truth is an epistemic notion (for example, truth is empirical confirmation in the long run, or verification by an ideal scientific community, or what is warrantedly assertible, and so on). Such antirealisms fall within the scope of the paradox, for these epistemic notions distribute over conjunction every bit as much as knowledge does, and their theory of truth makes these epistemic notions factives. So, the paradox can

be formulated in terms of the claims that some truths are not justified or verified in this special antirealist way, and that all truths are epistemic in the favoured antirealist way.

The paradox could be resolved in a way that retains both claims (1) and (2) above if knowledge fails to distribute over conjunction. The paradox requires moving from knowledge of a conjunction to knowledge of each of the conjuncts, that is, from K(A&B) to K(A) & K(B). Some theories of knowledge deny such a principle (for example, Nozick (1981)); however, these denials are not supported by independent argument but are rather only implications of the general theory. Because of this feature, the denial can easily appear to be a defect of the theory rather than a virtue. In any case, denying the principle requires a further explanation of the difference between cases where such distribution is acceptable and those where it is not, for it is clear that one can come to know, for example, that the George owns a car by learning that George owns a car and a truck.

3 The surprise examination paradox

The surprise examination paradox first appeared in print in D.J. O'Connor (1948). It originated earlier when a Swedish mathematician, Lennart Ekbom, discussed at Ostermalms College a difficulty he had noticed with an announcement by the Swedish Broadcasting Company during the Second World War. The announcement said that a civil-defence exercise was to be held during a particular week. No one was to know in advance which particular day of the week the exercise would be conducted. Ekbom noticed that the unexpectedness of the exercise was problematic, which forms the core of the surprise examination paradox. This paradox appears in many guises and under many names, including among others the 'prediction' and 'hangman' paradoxes. All have essentially the same form as that represented by the surprise examination.

Sceptical approaches to this paradox deny that the announcement of a surprise examination warrants any beliefs about the future. Thus, Quine (1953) maintains that even a surprise examination announced only one day in advance would not be paradoxical, for such an examination would be a surprise as long as one could not know in advance that the examination would be given tomorrow.

Non-sceptical approaches to the paradox grant that one can know on the basis of the announcement that an examination will take place. For such approaches, an examination given the last day of the week would thereby not be a surprise, contrary to the Quinean approach above. Such approaches, in order to resolve the paradox, must find something wrong with the announcement itself (Shaw 1958; Kaplan and Montague 1960) or with the inferences by the students (Meltzer 1964), for the paradox ends by having an examination occur that surprises the students. A standard approach following the first line is to show that the teacher's statement is self-referentially incoherent, as in the Liar paradox where 'This statement is false' is incoherent. For example, the announcement might mean or imply 'There will be a surprise examination next week, and there being no surprise examination is deducible from this entire statement'.

Such approaches have been rejected for violating a coherence requirement on the announcement (Bosch 1972), according to which it is plainly obvious that the announcement is coherent and hence that any adequate resolution of the paradox must locate an error in the students' reasoning.

More recent discussion has focused on different varieties of the paradox, and whether formal approaches to the paradox suffice to resolve it. In spite of being originally castigated as 'rather frivolous' (O'Connor 1948), this paradox has attracted by far the most attention of the epistemic paradoxes (nearly one hundred articles have been written on it, compared to only a handful for the others). Moreover, hardly anything uncontroversial is to be found regarding the paradox, including how to interpret the announcement, how to resolve the paradox, whether there is one or several paradoxes involved, whether the paradox is simply a variant of other well-known paradoxes, and what conditions a proper resolution of the paradox must satisfy. Some would hold that it is the deepest of the paradoxes; in any case, the attention it has received shows that it is far from frivolous.

Paranormal phenomena

The term 'paranormal phenomena' refers to the class of anomalous events studied within the field of parapsychology. Parapsychology's principal areas of investigation are extrasensory perception (ESP), psychokinesis (PK), and cases suggesting that personal consciousness survives the death of one's body. ESP phenomena are apparent instances of anomalous transfer of information. They divide into telepathy, clairvoyance and precognition. PK phenomena are forms, roughly speaking, of apparent mind-over-matter. Survival research deals primarily with cases of ostensible reincarnation and mediumship (or 'channelling').

The data of parapsychology raise a number of deep philosophical issues. Cases suggesting survival challenge materialist theories of the mind, and (according to some) provide good evidence for Cartesian dualism. ESP and PK challenge assumptions about the nature and temporal direction of causal relations, and also suggest the intimidating possibility that we have direct access to and influence on the thoughts and bodily states of others.

1 Varieties of paranormal phenomena

Paranormal phenomena, the phenomena investigated in parapsychology, are often called 'psi' phenomena. The term 'psi', an abbreviation for 'psychic', is considered by many to be more theoretically neutral than 'paranormal', 'psychic' or 'parapsychological': it seems to avoid issues about what should count as normal, and appears not to beg the question as to whether the phenomena under consideration fall naturally within the domain of psychology or whether they are explainable in physical terms.

Although the boundaries of parapsychology are not rigidly defined, it is clear that the field is concerned with anomalous phenomena falling into three principal areas of investigation. The first is the evidence for extrasensory perception (ESP). The study of ESP focuses on two sorts of phenomena in particular. 'Telepathy' is the influence of one person's mental states on those of another, other than by the usual or known means, and 'clairvoyance' is the similarly anomalous influence of a physical state of affairs on a person's mental states. For example, it would be a case of telepathy if a person's thoughts were directly caused by someone at a remote location thinking about something similar. It would be clairvoyance if a person's thoughts about a plane crash were directly caused by a distant plane crash. Although popular treatments of ESP suggest that telepathy and clairvoyance are types of anomalous knowledge (of remote states of affairs), philosophers and parapsychologists have long recognized that the evidence for ESP often suggests nothing more than anomalous types of causal interaction, without any sort of robust cognition deserving to be called 'knowledge'. For example, suppose that a burning house in another city caused one to have nothing more than - possibly incongruous - thoughts about fire or burning houses. If that occurs without the subject knowing that the house (or some house) is burning, it would be a manifestation of what C.D. Broad (1962) called 'clairvoyant interaction' rather than 'clairvoyant cognition'.

The second area of parapsychological investigation is psychokinesis (PK), often called 'mind-over-matter'. The study of PK concerns the apparent ability to produce physical effects independently of familiar or recognized sorts of intermediate causal links. These effects include the ostensible movement of remote objects, materializations (the apparently instantaneous production of matter), and apports (the apparently instantaneous relocation of an object). In cases of so-called 'macro-PK', as in poltergeist disturbances and mediumistic phenomena such as table levitations, the effects are produced on objects visible to the naked eye. By contrast, present-day laboratory investigations of PK study what is called 'micro-PK', the production of statistically significant nonrandom behaviour in normally random microscopic processes such as radioactive decay and thermal noise.

Although cases of apparent precognition should be classified as types of telepathy or clairvoyance, they raise distinctive issues about causality. That is because they suggest that an event (such as a plane crash) can causally influence an *earlier* state of affairs (say, a precognitive dream of the plane crash) (see Causation §7; Time travel §1). Of course, that interpretation would be resisted by those who are opposed to backward causation. In that case, if apparent precognitions cannot be explained away as mere coincidences or in terms of normal or familiar processes, two options remain. First, one could explain precognition as a form of unconscious inference based on contemporaneous information acquired by ESP. For example, the precognizer might have learned through ESP about the *present* state of the plane or mental state(s) of the passengers or crew, and that information might have surfaced to conscious awareness in a dream or premonition. Second, one might interpret precognition as a type of

PK, as telepathic influence, or both, by which the precognizer brings about the events apparently precognized.

The third area of parapsychological investigation deals with evidence suggesting the survival of personal consciousness following bodily death. Survival research focuses on cases of ostensible reincarnation and mental mediumship (that is, 'channelling' of information from an apparently deceased communicator). The evidence for survival consists primarily of anomalous knowledge of two sorts. First, some individuals demonstrate knowledge of facts or information which they presumably had no normal opportunity to acquire, and which concerns obscure or intimate details of some deceased person's life. Second, some individuals display skills or abilities - for example, speaking a language or playing a musical instrument - which they had no normal opportunity to acquire or develop, but which were associated with a deceased person either apparently communicating through a medium or apparently reincarnating in (or possessing) the person displaying the anomalous skills or abilities.

2 The challenge to materialism

Popular writings (and some philosophical works) on parapsychology often assert that the existence of paranormal phenomena would be evidence against materialist theories of the mental, and in favour of dualism (see Dualism; Materialism in the philosophy of mind). But that claim is somewhat contentious and in need of clarification.

It is important to note that there are at least two major forms of dualism. The first is Cartesian (or substance) dualism, according to which nature consists of two distinct kinds of stuff: mental (which is unextended and thinking) and physical (which is extended and unthinking). A somewhat weaker form of dualism is a level-of-description dualism, according to which nature may be described by means of either mentalistic or physicalistic vocabularies that are not entirely inter-translatable. For example, partisans of this weaker form of dualism might assert that nature consists of only physical stuff, but that the physical sciences have significant descriptive or explanatory limitations - say, in connection with the domain of mental states. (And that position can assume various forms. See, for example, Anomalous monism; Epiphenomenalism). Or, one could argue that nature is not inherently either mental or physical, but that different aspects of nature can be characterized relative to different vocabularies, or at different levels of description (see Neutral monism). Proponents of these two sorts of position could be thought of as substance-monists but level-of-description dualists. They illustrate how one can hold that mental phenomena generally are not adequately described or explained in physical terms, without claiming that the mind is a distinct kind of substance or thing. One might even say that 'the mind' is merely a general term for the class of mental events (or a certain aspect of what persons and some other organisms do), just as 'the weather' is a general term for the class of meteorological events (or a certain aspect of planetary phenomena).

Now initially, at least, it would appear that the phenomena of ESP and PK present no more of a threat to materialist theories of the mental than do everyday cognitive phenomena such as memory and volition. In fact, one can (at least hope to) handle the former just as many (at least hope to) handle the latter. The strategies would be the same in both cases. For example, one might concede that we cannot now specify the physical mechanisms underlying psychological phenomena generally, but then argue that somewhere down the road, a more sophisticated physical science will accommodate all such currently intractable phenomena. Or, one might attempt to specify underlying mechanisms or processes for the mental phenomena in question (for example, as many have tried in the case of memory and as some parapsychologists have attempted for at least certain psi phenomena). There are also many others who contend that mental phenomena generally cannot be explained with respect to underlying physical mechanisms or processes. One would think that from their perspective, the existence of ESP and PK pose problems of explanation no deeper than those posed by normal mental processes. Psi phenomena would be inexplicable in physical terms, but not in virtue of any of their features that are distinctively paranormal. As far as the physical sciences are concerned, they would be as intractable as the phenomena of memory and volition, and for the same reasons. Hence, although the forms of ESP and PK might support a level-of-description dualism, it would not be in virtue of their paranormality.

Some might argue that out-of-body experiences (OBEs) would support a stronger, Cartesian dualism. For example, suppose that a subject reports on a state of affairs visible only from the spot allegedly visited while ostensibly out of the body (there is some experimental and anecdotal evidence for this). And suppose that at the time of the experience, physical perturbations are detected at the spot where one's perceptual perspective seems to be, even though there is no object visibly occupying that position (there is preliminary experimental evidence for this as

well). Would that show that the mind is a thing that can leave and function physically apart from the body? In principle, one could argue instead that OBEs are nothing but imagery-rich clairvoyance, and that the physical disturbances can be explained as a form of accompanying PK.

Probably the only sort of parapsychological evidence that could clearly help support Cartesian dualism would be the evidence for survival. If it could be shown conclusively that consciousness survives the death and decomposition of the body, we might decide that this state of incorporeal existence can only be explained in terms of a mental substance. On the other hand, evidence of survival might equally be used to argue for a form of idealism, or a pluralistic worldview with an inventory of substance-kinds of at least three.

3 Problems of causality

Some might think that the phenomena of ESP and PK pose problems about causality because they would be examples of action-at-a-distance. But in fact, that issue worries few scientists and philosophers. Most would reject the claim that all causality is by physical contact (as in, billiard-ball causality), and some would, in any case, hold out hope for specifying the as yet undiscovered physical processes that allegedly fill in the apparent spatial causal gaps.

The most vexing problems about causality posed by the evidence concerns temporal direction. We have already noted that apparent precognition suggests that precognized events cause (earlier) precognitive experiences (although other explanatory options remain). In recent years, additional *prima facie* evidence for retro-causation has been provided by some provocative micro-PK experiments, designed and originally conducted by physicist Helmut Schmidt, and later replicated in other laboratories. These are experiments using pre-recorded random targets.

The general structure of such an experiment is as follows. Suppose that on day one a binary random number generator (that is, an electronic coin-flipper) is automatically activated (in the absence of anyone present) to record sequences of heads and tails onto audio cassettes, heads in the right channel and tails in the left. Suppose twenty such cassettes are recorded, and suppose also that a duplicate record of heads and tails is simultaneously produced on paper punch tape for the purpose of a permanent record. Then on day two, half of the cassettes are randomly selected to be test tapes, leaving the other cassettes designated as control tapes. At this point no one knows the contents of any of the tapes. On day three, the ten test tapes are played back to a subject who thinks he is taking a normal PK test with spontaneously generated targets. A computer counts the numbers of heads and tails (with a duplicate record once again being made on punch tape), and it turns out that the test tapes contain a statistically significant excess of heads over tails (and also that the effect size is similar to that demonstrated by subjects when all targets are being generated in real time). Then the control tapes are examined for the first time, and it turns out that they contain only chance levels of heads and tails (and also that both they and the test tapes match the punch-tape record for day one). But the only difference between the test and control tapes is that the test tapes were played for a subject making a PK effort. So it appears that the subject’s effort on day three biased the random generator on day one to produce an excess of heads only for the test tapes (whose selection as test tapes, recall, was not decided until later). In some follow-up experiments, it appeared that repeated playback of the pre-recorded targets to the subject (without the subject’s knowing this) seemed to increase the hit rate and improve overall PK scores. Schmidt called this an ‘addition effect’.

Once again, other explanatory options remain, even if one rules out explanations in terms of normal or familiar processes. For example, some have suggested that the results of these experiments could be explained in terms of clockwise (and presumably unconscious) psychic functioning, apparently on the part of the experimenter. Although some regard this sort of apparent ‘super-psi’ as antecedently incredible in its scope and refinement, others argue that it is not substantially different from what has been documented anecdotally (especially in the best poltergeist cases and cases of physical mediumship).

What many find most unsettling about the evidence for ESP and PK is that if these phenomena occur, then presumably they do not occur only in the lab, or when parapsychologists set out to look for them. They might be occurring surreptitiously or inconspicuously much of the time in everyday contexts and even in normal scientific research. In fact, reliable evidence for ESP and PK seems to force us to entertain seriously a ’magical’ worldview usually associated only with so-called primitive cultures, and according to which we have direct and intimate

access to and influence on the thoughts and bodily states of others.

Parapsychology

Tales of dreams that come true, 'mind over matter' and other such oddities are both familiar and old. Parapsychology investigates such things, attempting to use scientific and, especially, experimental methods to investigate whether and in what circumstances humans can glean information without using ordinary perceptual means (that is, by extrasensory perception or ESP) or can alter the physical environment simply by willing it (that is, by psychokinesis). Such phenomena, if they exist, are often grouped under the heading psi(-phenomena).

It is sometimes claimed that parapsychology presents a challenge to physicalism. However, ostensible psi-phenomena are known through their physical effects and are studied within parapsychology by ordinary scientific methods. In fact, models intended to explain psi-phenomena by known physical processes have been seriously discussed within parapsychology. In any case, parapsychology alone could not show that psi-phenomena have no physical explanation; that is a judgment for physics itself. More important, physicalism is a very broad doctrine that should not simply be equated with the requirement that everything be explained within physics. It is very unclear what we would gain by denying that psi-phenomena are physical.

1 Origins and method

Parapsychology has its roots in nineteenth-century investigations of spiritualism. Although parapsychologists still occasionally study spontaneous phenomena such as hauntings and individual so-called 'gifted' subjects who appear to have strong psychic abilities, the dominant tone of the field in the twentieth century was set by the American researcher Joseph B. Rhine, who opened his laboratory at Duke University in 1930. Rhine is responsible for such terms as 'extrasensory perception' (ESP) and 'psychokinesis'. He believed that the best way to investigate parapsychological phenomena was by the rigorous use of statistical methods, and he typically worked with ordinary subjects in experiments that involved simple choices among clearly distinguishable targets (for example, cards with a limited number of distinct symbols). He also emphasized questions about the psychological correlates of psychic ability and the factors that might inhibit or facilitate it. Rhine's work became the model for most parapsychological research thereafter.

The flavour of parapsychological research can be gleaned from an important example: the so-called *ganzfeld* (from the German for 'whole field') studies. In these experiments, the subject is put into a state of relaxation and mild sensory deprivation - a state that is hypothesized to be conducive to psi. Then an experimenter in a separate room concentrates on one of four randomly selected pictures. Finally, a second experimenter, who does not know which picture was viewed, shows copies of all four to the subject, who is asked to choose the one he thinks was the target. By chance, subjects should be right 25% of the time. The actual success rate is closer to 33%. This is a large effect by social science standards. If you could find a casino with these sorts of odds, you would win $130 for every $100 you bet. Across the many *ganzfeld* studies that have been performed up to the writing of this entry, it has been estimated that the observed effect would occur by chance roughly one time in a billion.

2 Parapsychology and physicalism

Clearly there are different sorts of questions one could ask about such experiments. Some have to do with the design of the experiment. Particularly important will be questions about procedures for preventing fraud and, more generally, what we might term 'sensory leakage' - cues detectable by the familiar five senses. Other questions have to do with statistical analysis, replication and randomization. Questions about randomization are particularly subtle and are the subject of some ongoing debate, but even some of parapsychology's harsher critics agree that there is no simple way to dismiss the *ganzfeld* experiments. However, beyond these methodological issues are questions about just how results of this sort ought to be interpreted assuming they stand up to scrutiny. In particular, do they undermine physicalism?

Rhine (1954), writing before the *ganzfeld* experiments, believed that the answer is yes. On the basis of his own work, he believed that psi-phenomena are not subject to shielding, do not diminish with distance and, in fact, cannot be explained by appeal to normal physical mechanisms. He speculated that, instead, they involve some sort of non-physical 'psi energy' that displays its effects by being converted into ordinary physical energy. Rhine welcomed this conclusion because he saw physicalism and what he took to be its attendant determinism as a threat

to freedom and responsibility (see Determinism and indeterminism; Dualism; Materialism in the philosophy of mind).

It is hard to see how Rhine's hypothesis of 'psi energy' could address his own concerns. It may be that freedom and responsibility require deliberation and other intentional phenomena to have a certain autonomy from the non-psychological (see Free will). This might argue against reductionism or eliminativism. But the connection between this claim and the existence of some supposedly non-physical means of propagating information or influence - 'psi energy' - is obscure at best. How would the ability to move things or know things with the help of 'psi-energy' add to one's moral freedom? Indeed, what would it have to do with deliberation and choice at all? Moreover, it is not at all clear how Rhine's hypothesis would render psi non-physical. Positing a new form of energy as part of the explanation for manifestly physical effects would seem to be a proposal for an addendum to physics itself.

In fact, nothing in the results of parapsychology provides clear reasons to think that parapsychological phenomena, if genuine, violate normal physical principles. This is not least because physicists have not given any sustained attention to the question of how such things might be explained. Here it is worth remembering that the history of science provides numerous examples of phenomena (magnetism, for instance) that once were thought beyond the pale of physics but which are now understood as unquestionably physical. But there is a more general point: the mere fact that we do not have an explanation of a phenomenon in terms of fundamental physics has never really been taken as a reason to count the phenomenon as non-physical. For example, thermodynamic phenomena counted as physical before statistical mechanics attempted to provide micro-accounts of such things as temperature and entropy (see Thermodynamics). Physics may never have much to say about economics, but by itself this hardly shows that physicalism is false, since physicalism is a much broader doctrine than reductionism and kindred notions (see Reduction, problems of; Reductionism in the philosophy of mind).

It might be thought that such examples fail to do justice to the worry. Whatever the details of a microscopic account of thermodynamic phenomena, the universality of the principles of thermodynamics makes it virtually impossible to imagine what could be meant by classing them as non-physical. And while economics may group things in ways that that make reduction to physics implausible (try to give a physical definition of 'money') nothing in economics suggests any obvious conflict with physics. Psi-phenomena seem very different. They seem anomalous, and anomalous in a particular way: they look essentially like action at a distance - information or influence travels we know not how from one point to another. That is the sort of thing for which we expect a mechanism or medium and which we also expect to satisfy a variety of physical principles such as conservation laws.

Suppose we found a replicable psi-phenomenon for which no mechanism was forthcoming and which persistently refused to mesh smoothly with the laws of physics. What then?

Our sense that such things as ESP and psychokinesis ought to involve a mechanism or medium is presumably part of a larger sense that they ought to be explainable, and that a satisfactory explanation would posit some process connecting the distant events. As it turns out, however, nature is not innocent of apparently unmediated connections. Within quantum mechanics there are strong correlations among distant events that seem to defy explanation by appeal to any reasonable mechanism (see Bell's theorem). While it must be stressed that these phenomena do not permit the sending of signals, they should at least caution us not to put too much stock in our intuition that all connections must be explained by appeal to a mediating process. It is debatable whether these quantum mechanical connections are *explained* in quantum theory - or anywhere else - at all. Still, there is a difference. Quantum mechanics is a fundamental theory and at that level we might expect explanation or perhaps even intuitive intelligibility to come to an end. Parapsychology deals with the macroscopic level, and that is not where we expect to bump up against the limits of explanation.

It is not clear how much weight to give such intuitions about the macroscopic. Once again, quantum mechanics is instructive. Given the fundamental laws of quantum mechanics, it is deeply puzzling that measurements, which are macroscopic events, actually have results at all (see Quantum measurement problem). Needless to say, attempts to solve the problem, whether by conceptual innovation or physical speculation, continue, but there is no guarantee that they will produce satisfactory results.

We might characterize physicalism in terms of some idealized final physics. If brute exceptions to the principles of that ideal physics had to be carved out to accommodate parapsychological phenomena, then it might be held that physicalism, construed as a doctrine about the hegemony of physics, was false. This would mean that principles and laws of physics would lack the sort of universality sometimes claimed for them, and it would mean that natural phenomena are less unified than we might have hoped.

However, just such things have already been argued by some philosophers of science on grounds quite independent of parapsychology. It has been argued that physics has no special rule in enumerating the kinds of things there are nor in generating the laws they obey (see Dupre 1993). It has been argued that the laws of physics themselves do not fit together in any smooth way. And it has been argued that the very idea of physical laws as features of nature rather than just features of the models we use is deeply suspect (see Laws, natural).

We have been asking whether parapsychological phenomena might conflict with physicalism. The answer is a resounding ‘Perhaps’. But suppose, hypothetically, that the answer is ‘Yes’. What then? Are such doctrines as Cartesian dualism (see Dualism) forced upon us? Must we regard parapsychological phenomena as supernatural? Have we discovered the limits of science itself?

The only sensible answer to each of these questions is ‘No!’ Nature may well be highly variegated, but positing a non-spatial mental substance is as uninformative in light of parapsychology as it is without it. Parapsychological phenomena are peculiar if genuine, but their manifestations are changes in the physical make-up or the belief states of natural things, including such things as ourselves. As it stands, the very existence of psi remains controversial and so any claims about psi, as well as any claims based on it, remain answerable to checking by means that rely ultimately on the familiar five senses. If, in some improbable future, psychic phenomena became so common and so robust that we could rely on them as we rely on more familiar means of gaining knowledge or altering the landscape, this would mean that there are more ways of coming to know and change the world than we had previously thought, but it is hard to see how this would demonstrate any limitations on science; if anything, it would augment its resources.

3 Conclusion

A healthy scepticism about parapsychological claims is perfectly reasonable. Psi-phenomena would, indeed, violate various common-sense expectations and parapsychology is a field in which fraud and wishful thinking have been special problems. Furthermore, there is something odd about a field whose subject matter is largely defined negatively. At the same time, the best of parapsychological research applies the same standards that hold in the rest of science. Psi-phenomena *could* precipitate a scientific revolution, but so might any number of other things. As things stand, the results are modest and the implications unclear. For now the appropriate response would seem to be to wait and see.

Pareto principle

A social state is said to be Pareto-efficient when there is no feasible alternative to it in which at least one individual is better off while no individual is worse off. The Pareto principle tells us to move from Pareto-inefficient to Pareto-efficient states. Suppose a large basket of fruit is shared among a group in some way or another - one apple, two peaches, a dozen cherries each, for instance. If the fruit can be exchanged so that at least some people get more enjoyment from what they have, and no one gets less, the Pareto principle instructs us to do so; indeed, it instructs us to carry on exchanging until no more improvements of this kind are possible.

The Pareto principle gets its name from the Italian economist Vilfredo Pareto (1848-1923), who showed that when a competitive market reaches an equilibrium, the outcome is Pareto-efficient, or a 'Pareto-optimum' (Pareto 1906). Pareto believed that valid interpersonal comparisons of utility are impossible, and so rejected the utilitarian view that a society is efficient when it maximizes aggregate utility. But each person could judge whether they were better off in state S1 or state S2, and so Pareto concluded that if everyone preferred S2 social welfare must be greater in S2, whereas if some preferred S1 and some S2, no such judgment could be made.

The Pareto principle has a weaker and a stronger form. The weaker holds that we should choose S2 in preference to S1 when everybody judges that they are better off in S2; the stronger holds that we should choose S2 when nobody judges that S1 is better, and at least one person judges that S2 is better. The weaker version requires that everyone gain if the change is to be a Pareto improvement; the stronger version requires only that some should gain and nobody should lose.

For many economists the Pareto principle seems to be self-evidently rational. How can we settle for a state of affairs when there is a feasible alternative that improves the position of some but worsens that of no one? The problem is rather that, seen as a criterion of efficiency, the principle is still too weak. In the real world there are likely to be many Pareto-efficient states to choose between, but here the principle gives us no guidance. If in moving from S1 to S2 many badly-off people gain but a few well-off people lose, we might think there is a gain in overall efficiency. But we cannot make such a judgment using the original Pareto principle alone (see Economics and ethics §3).

Philosophers have been less certain that the principle is a requirement of practical rationality. Two kinds of questions have been raised. Suppose that S1 represents a state of affairs that is distributively just by some criterion - for instance, each person enjoys an equal level of welfare. If in S2 some people are better off than in S1 but the criterion of justice is violated - welfare levels are no longer equal - it may not be irrational to choose Pareto-inefficient S1 over Pareto-efficient S2.

Second, Sen (1982) has argued that the Pareto principle may conflict with the liberal principle that each person should decide matters falling in their private domain, such as which position they sleep in. If people have strong 'meddlesome preferences' - that is, they are deeply concerned about what goes on in other people's personal domains - there will be cases in which the Pareto principle selects a social state that the liberal principle would exclude. This issue has now generated a substantial body of literature suggesting different ways of avoiding Sen's paradox.

Parmenides (early to mid 5th century BC)

Parmenides of Elea, a revolutionary and enigmatic Greek philosophical poet, was the earliest defender of Eleatic metaphysics. He argued for the essential homogeneity and changelessness of being, rejecting as spurious the world's apparent variation over space and time. His one poem, whose first half largely survives, opens with the allegory of an intellectual journey by which Parmenides has succeeded in standing back from the empirical world. He learns, from the mouth of an unnamed goddess, a dramatically new perspective on being. The goddess's disquisition, which fills the remainder of the poem, is divided into two parts; the Way of Truth and the Way of Seeming.

The Way of Truth is the earliest known passage of sustained argument in Western philosophy. First a purportedly exhaustive choice is offered between two 'paths' - that of being, and that of not-being. Next the not-being path is closed off: the predicate expression '... is not' could never be supplied with a subject, since only that-which-is can be spoken of and thought of. Nor, on pain of self-contradiction, can a third path be entertained, one which would conflate being with not-being - despite the fact that just such a path is implicit in the ordinary human acceptance of an empirical world bearing a variety of shifting predicates. All references, open or covert, to not-being must be outlawed. Only '... is' (or perhaps '... is... ') can be coherently said of anything.

The next move is to seek the characteristics of that-which-is. The total exclusion of not-being leaves us with something radically unlike the empirical world. It must lack generation, destruction, change, distinct parts, movement and an asymmetric shape, all of which would require some not-being to occur. That-which-is must, in short, be a changeless and undifferentiated sphere.

In the second part of the poem the goddess offers a cosmology - a physical explanation of the very world which the first half of the poem has banished as incoherent. This is based on a pair of ultimate principles or elements, the one light and fiery, the other heavy and dark. It is presented as conveying the 'opinions of mortals'. It is deceitful, but the goddess nevertheless recommends learning it, 'so that no opinion of mortals may outstrip you'.

The motive for the radical split between the two halves of the poem has been much debated in modern times. In antiquity the Way of Truth was taken by some as a challenge to the notion of change, which physics must answer, by others as the statement of a profound metaphysical truth, while the Way of Seeming was widely treated as in some sense Parmenides' own bona fide physical system.

1 Life and work

Parmenides lived and taught and, if the ancient tradition is reliable, framed legislation at Elea (modern Velia), a Greek city in southern Italy. His most eminent pupil was Zeno of Elea, author of the celebrated motion paradoxes. Plato in his *Parmenides* describes a visit by Parmenides and Zeno to Athens, usually thought to be around 450 BC, when he says Parmenides was aged about 65, Zeno about 40. He implies that Parmenides' work had been published a good deal earlier, since Zeno had defended it against its critics in his youth, perhaps around 470 BC. It could in fact have appeared as early as the 490s. In any case, the visit Plato describes is probably fictional, and the chronological details are open to suspicion (see Socratic dialogues §1). The only completely safe chronological assertion is that Parmenides wrote before Zeno, Anaxagoras and Empedocles.

About 150 lines survive from his poem, which was his sole published work. Most of these (around 107) belong to its first part, the proem plus the Way of Truth, which appears largely complete. The second part, the Way of Seeming, must originally have been at least as long. The numbered ordering of the fragments, established by editors, seems mainly reliable, but the original position of a few (especially fragments 3 and 5) remains controversial.

The language, which constantly exploits echoes of Homeric epic, is opaque and densely metaphorical. It will be impossible in what follows to do justice to many important questions of nuance. A further complication is that Parmenides is compelled to borrow for his arguments the very language of negation, change and differentiation which his conclusions will ultimately outlaw.

The Way of Truth is methodically argued. Although the opening describes Parmenides' journey to a goddess who

undertakes his enlightenment, this symbolizes less a religious revelation or appeal to mere authority than his own hard-won arrival at a god's-eye view, his intellectual odyssey of distancing himself from the familiar temporal world: he travels to the gates at which the paths of night and day meet, a mythically inspired vantage point which erases the alternation of night and day, together, we may suppose, with all the associated temporal and spatial distinctions. When the goddess proceeds to enlighten him, it is with a coordinated set of arguments. Her most favoured form of argument starts from the conclusion: *c*, because *b*, because *a*.

2 The three paths

An initial choice offered is between two paths. Later a third path, although not even represented as a formal possibility, has to be mentioned and blocked off because despite its incoherence it is the route which ordinary people actually try to take.

The first two paths are: '(It) is' (*esti*) and '(It) is not' (*ouk esti*). It turns out that you can only coherently say the former, and this in the later moves will radically restrict what can be truly said of that-which-is. But what is the status of this 'is'? In particular, does it have a subject and/or a predicate?

Unlike English 'is', its Greek equivalent *esti* can constitute a grammatically complete sentence, '(It) is', even when as here no explicit subject is supplied. At this initial stage, when we are still finding out what restrictions must be imposed on the character of whatever 'is', the failure to specify any subject term, even 'it' or 'something', looks deliberate. What, if anything, can stand as the subject of 'is' must not be in any way prejudged.

The Greek use of 'be' does not fall neatly into a complete or existential use ('*x* is') and an incomplete or copulative one ('*x* is *y*'). To be is, primarily, to be *something*, but this may be specified ('*x* is red', '*x* is a book') or left unspecified ('*x* is'). To a Greek ear these are not distinct senses; they also tend to shade into the so-called 'veridical' use, where 'being' means 'being the case', since the 'being' in question is viewed as once again copulative, *x*'s being *y*. It has long been disputed whether Parmenides' use of 'be' is existential, copulative, veridical or one 'fused' out of these. While some kind of fused usage looks likeliest, no confusion need arise from thinking of his poem as primarily an inquiry into what there is. At least, his description of that-which-is as ungenerated, continuous, immobile etc. suggests an object rather than (as on a narrowly veridical reading) a truth - indeed, an object which directly and successfully competes with the phenomenal world for the status of what-there-is.

There are few uncontroversial points of interpretation, but the opening argument can be paraphrased, with explanatory glosses, along the following lines.

There are two conceivable paths [that is, ways forward]*: to say '... is', and to say '... is not'* [these are actually presented as '… necessarily is' and '… necessarily is not'; contingency is assumed to involve an illicit conflation of being with not-being, and is therefore held over as a third path, see below]. *But saying '... is not' is not a way forward that you could ever actually explore* [that is, '… is not' is a predicate which can never be successfully supplied with a subject, by either (a) thinking of the subject or (b) naming it]. *This is because (a) you could not know that-which-is-not* [that is, you could not know what it is, since that-which-is-not is nothing; therefore you could not pick it out in thought as a subject], *(b) nor could you speak of it* [the nonexistent is not available for referring to]. *Besides, anything that you can speak of and think of* [that is, pick out as a subject term] *must be* [and is therefore automatically debarred from serving as subject of '… is not']. *This is because it is, at least, possible for it to be* [being conceivable, it at least *could* exist], *whereas for a 'nothing' to be is impossible* [there could never exist a non-existent thing]. *In short, '... is not' is a path that you could never travel* [an expression with no application] (frs 2, 6.1-3).

Likewise you can discount a third path, 'the one wandered by know-nothing two-headed mortals' [when they place their trust in the senses and accept a world of contingency, change and diversity]. *They 'consider being and not-being the same and not the same'* [since phenomenal things possess predicates only in certain respects, at certain times, etc., every case of being is also a case of not being; this is self-contradictory - see rule 2 in §3 - and/or entails the now outlawed not-being]. *It is a back-turning path. Do not out of habit follow it, relying on your senses, but judge by reason my refutation* [of it] (frs 6.4-9, 7).

3 The description of that-which-is

What follows is a journey down the one path that remains negotiable, the path of '… is' (fr. 8.1-49). Now that the inquiry has been focused exclusively on that-which-is, the goddess is ready to tell Parmenides *what* it is, and proceeds to enumerate its predicates. These, or perhaps the ensuing arguments for them, she calls the 'signposts' along the route.

On this path there are many signposts that it is [1] *unborn and unperishing*, [2] *a unique whole*, [3] *unshaken* [= unmoved], [4] *perfect/complete/balanced* [the text is disputed here, but §8 will tend to favour *atalanton*, 'balanced'] (fr. 8.2-4).

She immediately adds, '*Nor* was *it once, nor* will *it be, since it* is *now*, *one*, *continuous*.' It is controversial whether this is a fifth item on the list of signposts and, if so, where it is proved. It may be safer to regard it as her parenthetical justification of the preceding present tense '… it *is* unborn' etc., explaining that for an altogether undifferentiated entity a past and future cannot be distinguished from its present. It has been held that the move introduces the notion of timeless being. On another interpretation, 'now' signals that it still occupies time, but with the *passage* of time abolished - possibly foreshadowing the later notion of eternity. (On time, see also §7.)

Analogous to the question of time is that of space. Some would take the goddess's description of that-which-is to make it an altogether non-spatial entity, others a space occupier albeit without spatial distinctions. Is it an entity as innocent of spatio-temporal being as, say, the number 2, or something which occupies space and time but is nevertheless not subject to spatial and temporal distinctions? The following analysis will favour the latter, which not only is the more straightforward reading of the text but also allows the individual arguments to work better (especially those for predicates 3 and 4).

The favourite objection to a literal spatial reading has been that that-which-is will then prove to be a finite sphere, in which case it will have to be surrounded by vacuum or not-being, in contravention of Parmenides' own ban. However, this difficulty arises only given the starting assumption that space is infinite. That assumption became standard in Ionian philosophy (see Anaximander §2; Melissus §3), but is much less evident in the western Greek tradition to which Parmenides belongs: Empedocles, like Plato and Aristotle later, regarded the universe as a finite sphere bounded by the heaven, with no space, empty or otherwise, beyond it. The very notion of space as a self-subsistent entity with its own dimensions, slow to emerge in ancient thought, was probably unknown to Parmenides. Provided Parmenides' sphere is envisaged from within, like the familiar world with its apparently spherical sky, not from outside like an orange, the supposition of space beyond need not impose itself. Arguably, his spherical being is a radical redescription of our own spherical world, in which no feature beyond the shape itself survives.

At fragment 8.6-49 the goddess defends in turn each of the predicates of that-which-is. The arguments lean on two implicit rules.

Rule 1: no proposition is true if it implies that, for any *x*, '*x* is not' is, was or will be true. This draws directly on the preceding argument (see §2).

Rule 2: there are no half-truths (that is, no proposition is both true and false; no question can be answered 'Yes and no'). This may sound innocuous, but is used lethally to outlaw all qualified truths and ensure that nothing can possess a given predicate in one way (at one time, in one respect, etc.) but not in another, as is required by the variable world believed in by two-headed mortals. One might think that even in that world temporally or otherwise qualified propositions would obey rule 2, for example, that 'My egg is warm at 9 am' and 'My egg is not warm at 2 pm' could both be true without qualification. But Parmenides would insist that the unqualified proposition 'My egg is warm' is another which must obey the rule, and not come out true in a way, false in a way.

The arguments proceed as follows.

4 The denial of generation and destruction

It cannot [taken as a whole] have had a beginning, since (a) that would have been from previous not-being [rule 1], *and (b) there could have been nothing, prior to its generation, to make it come into being precisely when it did, rather than sooner* [a celebrated anticipation of the Principle of Sufficient Reason] (fr. 8.6-10).

Likewise it must be totally or not at all [rule 2; that is, it cannot be generated piecemeal]: *no additional bits can*

come into being, since that too would be from previous not-being [rule 1] (fr. 8.11-14).

Thus both generation and [by parity of reasoning] *destruction are excluded* [In both wholesale and piecemeal destruction something comes not to be, contravening rule 1. But there is no obvious analogue to (b) above, the Principle of Sufficient Reason: in that-which-is there might well, for all we know at this stage of the argument, be sufficient reason for destruction to occur later rather than sooner, for example, progressive decay.] (fr. 8.13-21).

5 Continuity

It is also indivisible [or perhaps 'undivided']. *This is because it is completely homogeneous, its continuity not disrupted by varying degrees of being* [This would entail corresponding degrees of not-being, contrary to rule 1. Since it cannot to any extent not-be at one point what it is at another, there is nothing true of any individual part to distinguish it from any other part. So talk of 'parts' becomes empty.] (fr. 8.22-5).

6 Immobility

'Motionless, in the limits of mighty bonds', (a) 'it is unstarting and unstopping' [it neither starts off nor comes to a halt], *because coming-to-be and perishing have already been refuted* [and starting is the coming-to-be of motion, stopping is the perishing of motion]. *And (b) it stays just where it is, held by Necessity 'in the bonds of a limit which imprisons it all round'* [that is, that-which-is, taken as a whole, does not move anywhere, because it entirely fills its own spatial boundary, leaving itself no room to move]. [And it must have this boundary] *'because it is not fitting for that-which-is to be incomplete'* [absence of a definite boundary being a form of incompleteness]. *This in turn is because 'it is not lacking: if it were, it would lack everything'* [and therefore not exist at all; by rule 2, it cannot be both lacking and not lacking] (fr. 8.26-33).

This argument is often read as one against change in general; but the language strongly suggests that motion is the target. (Nothing in it specifically excludes the perpetual rotational movement of a sphere, but would this be conceivable in an entity with no distinct parts (see §5)?) Its 'boundary' argument works better for motion than for other forms of change. Parmenides' general objection to change may be located not here but in his arguments against generation (see §4), where the denial of piecemeal generation could well include that of new properties.

7 Monism

So far the goddess has defended predicates 1, 2 and 3 (see §3). The next lines, fragment 8.34-41, are difficult and controversial. They appear to interrupt the sequence of arguments, with the proof of predicate 4 not beginning till line 42. Some regard them as somehow part of that proof, others as a summary of results so far, yet others as a digression against empiricism. A still likelier explanation is that before she can embark on her final proof, concerning the shape of that-which-is, the goddess must pause to establish formally its *singularity*. She has already demonstrated that it itself forms an undivided whole, but she must still show that neither (a) thought, nor (b) time, nor (c) the plural objects of the phenomenal world, can be anything over and above it. The following paraphrase suggests how.

(a) *Thinking is identical with that which prompts thought* [that is, its object, being]. '*For in what has been said* [that is, the preceding arguments] *you will not find thinking separate from being*' [It has been seen that thought and being always go together, since not-being is unthinkable. There are no grounds for distinguishing the thinking subject from the object thought. Thinking is being and being is thinking. See also fragment 3 (of uncertain location) - *'For to think and to be are the same'* - which has often been given other, somewhat strained, translations to avoid this admittedly very difficult notion.] (fr. 8.34-8).

(b) *'Neither is there, nor will there be, time* [for the reading of the text, see Coxon (1986)] *over and above being, since Fate has bound it down to be the whole* [hence spatially all-inclusive, so that there can be no external measure of time] *and unmoved* [so that there can be no internal measure of time].'

(c) *'Therefore* [since that-which-is is all-inclusive and motionless] *it* [that-which-is itself] *has been named all the things which mortals have posited, believing them to be real' and to undergo changes of all kinds* [That is, when ordinary people talk about empirical objects, properties etc. they are speaking, not (impossibly) of nothing, but of that-which-is, even if they are radically misdescribing it. So the fact that ordinary talk is about something does not mean that there is something over and above that-which-is for it to be about.] (fr. 8.38-41).

Whether or not posterity was right to proclaim Parmenides the champion of the One against the Many, he was undoubtedly a monist. But Monism as such was not new. All his major forerunners, from Thales to Heraclitus, had believed everything to be ultimately analysable as manifestations of one thing, namely a single underlying stuff. Parmenides was the first *eliminative* monist. Everything is still one, but in a way which, instead of accounting for plurality, eliminates it.

8 Symmetry

'But since there is an outermost limit [see §6]*, it is bounded on all sides, like the mass of a well-rounded ball, being equally balanced on all sides from the centre* [that is, it is spherical in shape; many interpreters make it resemble a sphere in some other way than shape, for example, in perfection or uniformity, which risks underplaying this geometrically precise description, and makes the grounds which follow less apposite]. *For it must not be bigger or smaller here than there* [it cannot be asymmetrical, as it would have to be if not a sphere]. *For there is no not-being to prevent it reaching the same distance'* [if it were cut off short in one direction, that would mean its not-being beyond that point, in contravention of rule 1], *nor are there degrees of being* [it cannot be asymmetrical by thinning out in places], *because it is, as a whole, 'immune'* [to depletion], *having precisely equal being throughout, up to its limits* (fr. 8.42-9).

This ends the Way of Truth. Can the goddess really be telling Parmenides that that-which-is is literally spherical, without jeopardizing its partlessness? In a sphere you can distinguish hemispheres, segments and other parts. True, but at least the sphere is the one solid that you *can* think of as a whole without distinguishing parts (contrast, for example, a cube, which must be thought of with eight corners etc.). And the upshot of the poem so far, with its attack on human perspectives, has been to persuade Parmenides not to try to enforce any such distinctions. See also fragment 4 (of uncertain location): *'Gaze in thought equally upon absent things as firmly present. For thought will not split off that-which-is from clinging to that-which-is, scattered or gathered everyhow everywhere in the world.'*

9 The Way of Seeming

The goddess now turns to the 'opinions of mortals', and sets out, unargued, an analysis of the phenomenal world in terms of the combination of two opposite 'forms' or elements, one light and fiery, the other heavy and dark. The surviving fragments are scanty, but the cosmology includes the following: a role for a creative goddess, a detailed description of the heavens as a set of concentric bands, an embryology and a physiology of human thought.

The Way of Seeming has been promised by the goddess from the outset: *'You must find out everything - both the unshaken heart of well-rounded truth, and the opinions of mortals. In them there is no true trust, but you must learn them too anyway…'* (fr. 1.28-31). At its opening she calls it 'deceitful', if also 'plausible'. She adds that Parmenides must learn it *'so that no opinion of mortals may outstrip [or overtake] you'* (fr. 8.61), apparently meaning that the cosmology will be the best of its kind, able to compete successfully with those already offered by others. And there can be no doubt that this part of the poem is, for whatever reason, making an original contribution to cosmology. It even incorporates two major astronomical discoveries: that the Morning Star is identical to the Evening Star, and that the moon's light comes from the sun. But if all cosmology is false, what is the point of even entering such a contest?

Where Parmenides' major predecessors had been material monists, Parmenides offers his own distinctively dualist scheme. So his analogous move from one entity in the Way of Truth to two in the Way of Seeming is anything but casual. Indeed, the arithmetical point is precisely what the goddess emphasizes: mortals *'have made up their minds to name* two *forms, of which they should not name* one' (fr. 8.53-4). This, although sometimes taken to mean that they should not name *so much as* one, or even not *merely* one, is most easily read as saying that precisely one out of the two is a mistake. That itself, if correct, might be understood as purely numerical: any total of two is one too many. Or it can be taken specifically: one of these two forms is identical with that-which-is, but the other should not have been added - in which case it becomes tempting (and Aristotle among others was tempted) to assimilate the illicit second element to what in the Way of Truth was called not-being. As to which element is which, it is usually the fiery element that is assumed to correspond to that-which-is, although Popper (1992) has advocated the dark heavy one, in which the fiery one produces the mere semblance of change, just as the moon, in reality solidly spherical, was known by Parmenides to appear to wax and wane through the play of light on it.

The question remains how the cosmology relates to the Way of Truth. Some have held that it itself contains a measure of truth, others on the contrary that it is there to expose the patent falsity of any departure from strict monism. Of these, the former sits ill with the goddess's contrast between mortal opinions and truth, while the latter conflicts with the fact that the cosmology, rather than being *patently* false, is highly 'plausible'. A more attractive possibility is that she wants to show how surprisingly similar the deceptive empirical world is to the stark Way of Truth. The whole range of cosmic phenomena can be generated by allowing the intrusion of just one additional item - by starting out with two instead of one. This hypothesis makes good sense of the often noticed fact that the cosmological descriptions in the Way of Seeming pointedly echo the language of the Way of Truth. For example, the description of the *'encircling heaven'* as *'bound down by Necessity to hold the limits of the stars'* (fr. 10) recalls that of that-which-is as held motionless by Necessity in the bonds of a limit (see §6).

Thus interpreted, the Way of Seeming does not pretend to vindicate phenomena, but it does tackle the biggest headache faced by any convert of Parmenides: how can human experience have got things quite so catastrophically wrong? The answer is that the step from appearance to reality is much smaller than it may initially look.

This admittedly still does not begin to explain how the error of mortals ever occurred. If Parmenides is right, there are no separate thinking subjects. All thought is that-which-is thinking itself. How it could find room to misconceive itself is a question on which Parmenides leaves us to puzzle.

10 Influence

Parmenides marks a watershed in Presocratic philosophy. In the next generation he remained the senior voice of Eleaticism, perceived as champion of the One against the Many. His One was defended by Zeno of Elea and Melissus, while those who wished to vindicate cosmic plurality and change felt obliged to respond to his challenge. Empedocles, Anaxagoras (§2), Leucippus and Democritus framed their theories in terms which conceded as much as possible to his rejections of literal generation and annihilation and of division. On the other hand, in this they were swayed less by Parmenides' own primary argument, the inadmissibility of '… is not', which won few converts, than by an older and less controversial premise, the impossibility of generation *ex nihilo*.

Plato (§16), in his *Sophist*, did take up puzzles raised by Parmenides' rejection of not-being. But it was in recognition of Parmenides' rigorous methodology, not his doctrines, that in his later work Plato expressed a degree of allegiance to the Eleatic tradition, letting Parmenides or an unnamed follower of his eclipse Socrates as principal speaker in three major dialogues.

Plato's own declared veneration of Parmenides is exceeded by that of the Neoplatonists, who treat his 'one being' as an integral part of their own metaphysical hierarchy. Among his modern admirers, perhaps the most prominent is Heidegger, for whom Parmenides was the last great thinker before the 'forgetting of being' which has blighted the subsequent history of metaphysics.

Particulars

Particulars are to be understood by contrasting them with universals, that term being used to comprise both properties and relations. Often the term 'individuals' is used interchangeably with 'particulars', though some restrict the term 'individuals' to those particulars whose existence has more than momentary duration.

It is sometimes taken as a distinctive feature of particulars that they cannot be in more than one place at a time, whereas universals are capable of being wholly present in more than one place at a given time: if you have a white thing here and a white thing there, then you have two particulars but only one property. This way of distinguishing between particulars and universals may help us to focus on apt paradigm cases of each, but arguably this does not get us to the heart of the matter. On the one hand, some think it is possible, at least in principle, for a magician, or Pythagoras, or a time traveller, or a subatomic particle to be in two places at once, even though each is a particular. On the other hand, some think that there are properties which could not possibly be manifested in two different places at the same time, and yet which nonetheless are universals: think, for instance, of the divine property of absolute perfection, or of the conjunction of all intrinsic properties of a Leibnizian monad (or possible world); or of Judas' property of simply being Judas.

Particulars are things which have properties and which stand in relations - particulars 'instantiate' properties and relations. By itself, however, this does not distinguish particulars from universals since universals, too, are naturally thought to have properties and to stand in relations. What distinguishes particulars is the fact that, while a particular instantiates properties and relations, nothing instantiates a particular. Universals both 'have' (properties and relations) and are 'had'; particulars 'have' but are not 'had'. Since a particular is not instantiated by another thing, it is sometimes said to exist 'in itself', whereas a universal exists 'in' something else. For this reason, the term 'particular' is related to the term 'substance', which is traditionally used to mean something capable of independent existence.

1 What is at stake

In some of his dialogues, Plato seems to assume that nothing is real, knowable or of value unless it is permanent (see Plato §15). The particular things we experience through the senses are all impermanent; so Plato infers that these particulars are unreal, unknowable and of no value. The things which are real, knowable and of value are the moral, political, aesthetic and mathematical ideals which individual people, social groups and works of art may aspire towards but never really embody perfectly - the Forms.

In an ancient Buddhist text, the existence of common-sense particulars is called into question (Horner 1963: 34-8; Eliot 1910: 668-72). Suppose, for example, that you reach out and touch something, saying 'This is a chariot'. The ancient sage calls attention to the fact that what you are touching is, more strictly, a wheel, and more strictly still, a hub, spoke or rim, and of course only the surface of that. So there is really no such thing as a chariot; and the same goes for other particulars, including persons. A person is like a flame, or an eddy in a river - there is nothing which persists through the passage of time. Particulars are only shadows cast by quirks of Indo-European syntax, with no more substantiality than the 'It' in 'It is raining'.

In contrast, for Descartes there is nothing more certain than the existence of the self: his philosophy rests on the famous inference 'I think, therefore I am'. Western liberal democracies place great store, at least in theory, on the importance of the individual. In the arts, a conception of individual artistic genius has held us in a tight grip. And modern mathematical logic rests heavily on names and variables which are interpreted as picking out individuals from a domain of discourse. In a great many ways, individuals, or particulars, are central to our thinking, not only about this world of impermanence but also about the timeless truths of mathematics. Many philosophers are therefore diametrically opposed to the Platonic or Buddhist deflation of particulars.

2 Bare particulars

Aristotle agreed with Plato that knowledge - science - is concerned with things which are necessary and hence permanent. Yet for Aristotle this did not exclude knowledge of particulars. Admittedly, each particular is subject to generation and corruption; nonetheless, each particular does have certain essential properties in virtue of which it belongs to a species and genus. And although individuals are transient, species are permanent. Individuals can be

subjects of knowledge, thanks to their possession of essential properties (see Aristotle §§14-15).

Aristotelian essentialism is often disavowed by philosophers but, arguably, essentialist assumptions are pervasive in our thinking at both a common-sense and a philosophical level. The essentialist holds that each particular has certain properties which it cannot lose except by ceasing to exist, and which it could not have lacked from the start except by never having come into being. The contrary doctrine is sometimes called the doctrine of 'bare particulars' - that particulars do not have essential properties. Although essentialism is regularly disparaged by philosophers, so is the contrary doctrine of bare particulars. The rejection of both together would require a radical elimination of the very idea of any but merely verbal necessities or possibilities, as in Quine (1953).

3 Bundles of properties

Consider a particular which has several essential properties and several accidental properties. There is room to consider a theory which identifies the particular with the collection of essential properties, and there is room to consider a theory which identifies the particular with the collection of all its properties. On consideration, however, it can be seen that a particular cannot be identified with any collection which includes an accidental property. An accidental property is something which, by definition, the particular could have lacked. But the bundle of properties which includes that accidental property would not have been the bundle that it is if it had not included that property.

Consider, therefore, the theory which identifies a particular with the collection of its essential properties. An objection can be raised if we show that there can be several particulars which share exactly the same essential properties. Certainly Aristotle thought that different members of the same species share the very same essential properties. For Aristotle, therefore, what distinguishes particulars of the same species is not their 'form', but the 'matter' on which this form is impressed.

Hence if we are to identify a particular with a collection of essential properties, we must suppose that distinct particulars cannot ever share exactly the same essential properties. Each particular must have some property which no other particular could have. This is what is called an individual essence. One way of thinking of an individual essence is by construing it to be an unshareable conjunction of severally-shareable properties as, for example, Leibniz's monads. An alternative would be to suppose that for each particular there is a simple essential property called a 'haecceity' (from Latin, meaning 'thisness') which that particular alone possesses and which nothing else could have had either instead of or as well as it. This notion was articulated by the Islamic philosopher Avicenna (see Ibn Sina §4), and was taken up by some of the scholastic philosophers in Europe, such as Duns Scotus in the thirteenth century, but has been roundly denounced by many since that time.

4 Properties particularized

There is thus a line of argument which leads from the stereotypically empiricist idea that a thing is a bundle of properties to the distinctly non-empiricist doctrine of haecceities or individual essences. An empiricist can avoid inconsistency by particularizing properties.

For the sake of illustration, suppose coldness to be a typical property of a thing. According to some philosophers, then, the coldness of one block of ice is one thing, and the coldness of another block of ice is quite another thing. It is not just that the second block of ice is a second instance of a cold thing but, rather, the coldness of the second block of ice is a second instance of coldness. Whenever something is cold, there exists something which we may call its coldness: this may be called a 'property instance' or (following D.C. Williams) a 'trope'. According to the trope theory, a particular can be taken to be a 'bundle of properties' provided we take each of these properties to be an abstract particular.

The trope theory is a contender for, but has not attracted, majority support. Some of the Scholastic nominalists, like Ockham, can be read as having articulated such a view, and the view has been revived by a series of philosophers in the twentieth century: a classic exploration is found in Nelson Goodman's *The Structure of Appearance* (1951) (see Nominalism §§2, 4).

5 Particulars as aggregates

Emergentism is the doctrine that something new emerges or comes into being when materials come together and

take the form of something with a kind of unity and persistence across time, as for instance a living being. Such a thing is constituted by a plurality of parts, but is something distinct from just the aggregate of those parts.

The distinction between a thing and the aggregate of its parts can be drawn by reference to their logical independence: you could have had either one without the other. Consider a particular ship, say the ship of Theseus. This ship is constituted by planks of wood. But the planks could have existed without ever constituting a ship; and the ship could have been constituted by different planks. Hence the ship is not the same thing as the aggregate of the planks which constitute it.

This conception of an individual as something other than just the aggregate of its parts has been bedevilled by a puzzle, famously described by Hobbes (Molesworth 1837-45 (4): 135; the example traces back to Plutarch's 'Life of Theseus' §§22-3). Suppose that, over time, worn planks on the ship of Theseus are replaced by new ones, and a working ship is maintained in continuous existence; meanwhile, the worn planks which are taken away are gradually reassembled in just the way they were arranged in the original ship. One principle leads us to say that the working ship with new planks is the ship of Theseus; another principle leads us to say that the reassembled ship with worn planks is the ship of Theseus. Yet an individual ship cannot be in two places at once: which of them is the ship of Theseus? This ship puzzle can be paralleled by puzzles of personal identity across time (see Personal identity).

Objections of this sort have been raised against the theory that there are particulars which have parts, but which are not just the aggregates of those parts (the contrary theory takes all particulars to be just the aggregates of their parts). Goodman and Quine (1947) have been very influential in promoting the idea that particulars are best understood through the theory of the part-whole relation, or mereology (see Mereology). Furthermore, according to Goodman, Quine and others, an individual which persists through some interval of time has distinct parts existing at each distinct time in that interval. Among the things which exist at one time is a timeslice which exists only at that time; among the things which exist at another time is a different timeslice; the thing which exists across several distinct times is just an aggregate of distinct timeslices.

Hobbes' puzzle question, 'Which is the ship of Theseus?', is then diagnosed as turning upon a merely verbal vagueness. There are two distinct aggregates which are broadly ship-shape, and it is mere semantic indeterminacy which makes us unsure as to which of them should be called 'the ship of Theseus'. Similar reasoning applies equally to persons.

6 The state of the art

Strawson (1959) draws a distinction between 'revisionary' and 'descriptive' metaphysics. In revisionary metaphysics, a theory is advanced to replace our ordinary language and thinking. In descriptive metaphysics, a description is given of the deepest presuppositions of our existing theories. Using these criteria, the broadly Aristotelian theory does seem to qualify as a relatively descriptive theory, by contrast with Plato's more revisionary claims that particulars are unreal, unknowable and of no value. The Aristotelian theory is also more descriptive than theories which deny that particulars have essential properties, theories which take particulars to be bundles of tropes and theories which treat all particulars as merely the aggregates of the spatial and temporal parts out of which they are constituted. The more revisionary theories may be right; but the more conservative theories still have a lot of life left in them. The time is not ripe for a consensus to emerge on the nature of particulars.

Partiinost’

Partiinost’ *(Russian for partyness, often translated as party-mindedness, partisanship or party spirit) was long the controlling principle of Soviet Marxism. Though commonly identified with thought control,* partiinost’ *originally signified social analysis of thought joined with moral judgment, an ancient combination that can work against the powers that be as well as for them. Lenin’s version changed from revolt to thought control after his party came to power in 1917, but especially after Stalin’s ‘revolution from above’ twelve years later. In 1950 Stalin began a restriction of* partiinost’ *by declaring ‘science’ separate from ‘ideology’. Such reform accelerated after his death in 1953, but slowed down from the mid-1960s to the late 1980s. Then a new burst of reform set off the collapse of the Soviet system and of* partiinost’*, though the problems that engendered it - the entanglement of group interests and claims of truth - persist.*

The self-serving nature of group beliefs has often been exposed. Xenophanes on divinity (‘If oxen could paint, their gods would be oxen’), Thrasymachus on justice (‘the interest of the stronger’) and Thomas More on ‘a conspiracy of the rich, who pursue their own aggrandizement under the name of the commonwealth’, are famous examples. Hobbes distinguished between ideas that involve interests - such as justice - and ideas that ‘cross no man’s ambition, profit, or lust’, such as the sum of angles in a triangle. He added however: ‘If [that sum] had been… contrary to the interest of men that have dominion… it would have been, if not disputed, yet by the burning of all books of geometry, suppressed, as far as he whom it concerned was able.’ Thus his sociology of ideas included a bellicose determinism: a ruling party is compelled to suppress thought that threatens its interests. He had seen parties or ‘factions’ bring civil war; the only remedy was for the sovereign to suppress them.

‘Party’ has not always meant factiousness. Shakespeare imagined the War of the Roses brought to an end by those who ‘dare maintain the party of the truth’, and the philosophers of the Enlightenment have been praised as ‘the party of humanity’. The emergence of modern parties, as special-interest groups engaged in routine contests for power, made identification of a party with the interests of humanity seem threadbare rhetoric, hardly concealing the sordid realities of partisan self-seeking. That may be one reason why *Das Kommunistische Manifest (The Communist Manifesto)* of 1848 declared that ‘the Communists do not form a separate party opposed to other working-class parties’.

Marx and Engels were political isolates without a significant party, not only in 1848 but through most of their lives, in part because they admired the scholar who seeks all-human truth rather than the ‘party man’ who serves special interests. Belief in disinterested inquiry mingles in Marx’s writing with insistence that ideology is unavoidable when class interests are entangled with claims of reason. Only the proletarian overthrow of class rule will bring the end of class bias in ideas. In that march towards truth the manifesto of 1848 says that Communists do not ‘form a separate party’, but they are ‘the most advanced and resolute section… of the proletariat, [who] have over the great mass… the advantage of clearly understanding the line of march, the conditions and the ultimate general results of the proletarian movement’. Thus Marx in 1848 laid out a rationalization of *partiinost’* for Communist Party-states of the twentieth century.

But that *is* a rationalization, which ignores contrary elements in Marx’s thought and in its uses, both for liberal pluralism by Marxists in Germany and for one-party tyranny by Marxists in Russia or in China and other ‘underdeveloped’ places. Liberal pluralism has emerged mostly in ‘developed’ lands, often through protracted experience of civil war, while Hobbesian choices between civil war and autocracy have attended the spread of party politics to places perceived as ‘backward’, in acute need of drastic ‘development’.

In nineteenth-century Russia talk of *grazhdanstvennost’*, citizenship, as something to be created through organized struggle, foreshadowed *partiinost’*. Chernyshevskii opened ‘Antropologicheskii printsip v filosofii’ (The Anthropological Principle in Philosophy) (1860) with a declaration that ‘every philosopher has been a representative of one of the political parties struggling in his time for predominance over the society to which the philosopher has belonged’. Even P.L. Lavrov, the Russian radical who exalted the ‘critically thinking individual’, enjoined such a thinker to serve ‘the people’ through a party, ‘to devote his energies to this party and to be guided by its advice’. ‘Party’ here signified commitment to a dream of an ideal system, which provoked splits as readily as organizations among fellow dreamers. Party discipline, often preached, was an additional impetus to splitting.

Trotsky's famous warning against Lenin's version of such discipline - that it would replace the working class by the Party, the Party by the Central Committee, the Central Committee by the dictator - could come true only with the accession to state power (see Lenin, V.; Trotsky, L.).

In 1895, when Lenin first used the word *partiinost'*, Russia was an autocracy without political parties. He was criticizing a fellow Marxist for showing the inevitability of capitalism but not its evil, though objectivity requires condemnation along with explanation. 'Materialism includes, so to speak, *partiinost'*, obliging one in any judgment of an occurrence to take directly and openly the viewpoint of a definite social group'. Like Chernyshevskii and Lavrov, Lenin was pointing to a fellowship of belief rather than a concrete political organization, and that was still his usage in *Materializm i ėmpiriokrititsizm (Materialism and Empiriocriticism)* (1909). By that time a Marxist party had been formed, and had split into Bolsheviks and Mensheviks, but Lenin's book assigned all philosophers to two 'parties' of a much broader kind: idealists and materialists, who had been serving the interests of rulers and ruled, of faith and science, since ancient times.

With that crude class analysis of philosophical schools Lenin justified the expulsion from the Bolshevik organization of comrades who rejected the dialectical materialism that he had learned from Plekhanov, a Menshevik in party affiliation. Lunacharskii, one of the expelled Bolsheviks, challenged Lenin to acknowledge his break with a rule laid down by Bebel, a German Marxist leader:

> 'We have no dogma and therefore cannot have heretics'. Let us grant that Bebel was mistaken, that both heresy and its condemnation are a possible phenomenon in Social Democracy. But don't we have the right to expect that in our Party free thought will have at least the same guarantees as are given to it by the Catholic Church, which prides itself on its intolerance?
>
> (Joravsky 1961: 39)

Lenin ignored that demand for precision and due process; *partiinost'* was casually invoked, never carefully analysed, even after 1917, when his party won power and suppressed rival parties.

At first the Central Committee limited its efforts to control intellectual life. Its ideological bureaucracy correlated ideas with the interests of social classes rather than parties in the literal sense, and did not try to enforce strict uniformity on thinkers. Such laxity was assailed in a 'discussion' following Stalin's complaint, in 1929, that 'theorists' were not adequately serving 'practicians', whose 'chief' (*vozhd'*) he was. Henceforth he would be 'chief' of 'theorists' as well, philosophers included. 'The basic lesson of the philosophical discussion', as an ideological official (Kol'man) explained to mathematicians, was to end 'all efforts of any theory, of any scholarly discipline, to conceive itself as an autonomous, independent discipline… isolated from Party guidance'.

Philosophy became commentary on speeches of Stalin or decrees of the Central Committee, while ideological bureaucrats complained that the commentary was timid and unoriginal, and that it was subversive to limit *partiinost'* by attempting careful distinctions between science and ideology. The 'primacy of practice' required philosophers to dig up quotes from 'the classics of Marxism-Leninism' showing that the changing intuitions of Party leaders were justified by theory as well as practice. In short, an anti-intellectual, authoritarian pragmatism was the heart of Stalinist *partiinost'*. One of its effects was an ironic inversion of the social analysis of thought compacted with moral judgment, which had once been the meaningful core of the concept. Ferocious attacks on individualistic thinkers regenerated admiration of the type, while servants of 'the people's party' came to be regarded as immoral lickspittles, saying nothing of substance.

The stultifying effects on intellectual life, including the creative expertise demanded by practical leaders, brought Stalin to call a retreat. In 1950 he announced that 'no science [*nauka*] can develop and prosper without the clash of opinions, without freedom of criticism', a 'generally recognized rule that has been ignored and violated in the worst way'. Of course he blamed 'petty despots' in charge of particular disciplines, not the Central Committee or the concept of *partiinost'*, but he opened the way to restriction of the concept by declaring that 'science' or 'scholarship' (*nauka*) was not part of ideology. Efforts to spell out such restriction were feeble until Khrushchev began 'de-Stalinization' after Stalin's death in 1953. Even then Soviet philosophers were much more timid than their Polish and Yugoslav comrades. Kolakowski was especially forceful in showing the absurdities of 'institutional Marxism', which insisted that the intuitions of Party chiefs were infallible products of a scientific ideology.

The ouster of Khrushchev in 1964 checked further debate until the late 1980s, when another reformist party chief, Gorbachev, began a campaign for ‘openness’ and ‘restructuring’. That led so swiftly to systemic collapse that serious discussion of *partiinost’* hardly began. It became instantly extinct, remembered only to be denounced or renounced by the minority of Russian thinkers still sympathetic to Marxism in some form. Serious inquiry in the sociology of knowledge, including the complex interdependence of group interests and claims of truth, is barely beginning to address the record of *partiinost’*, whether in Russia or in other Communist countries.

Pascal, Blaise (1623-62)

Blaise Pascal was a mathematical prodigy who numbered among his early achievements an essay on conic sections and the invention of a calculating machine. In his early twenties he engaged in the vigorous European debate about the vacuum, undertaking, or causing to be undertaken, a series of experiments which helped to refute the traditional view that nature abhors a vacuum and setting out clearly the methodology of the new science. In 1646 he came under the influence of Jansenism; this he seems to have rejected for a short time in the early 1650s, but he then underwent a profound spiritual experience which transformed his life and drew him into close association with leading Jansenists, with whom he collaborated in producing the polemical Lettres provinciales *(1656-7). At the same time he planned to write an apology for the Christian religion, but ill-health so affected his final years that this only survives in the fragmentary form of the* Pensées *(1670). He made significant contributions to mathematics, especially in the fields of geometry, number theory and probability theory, and he also helped to describe the* 'esprit géométrique' *which characterized the new science of the 1650s. He argued that geometry was superior to logic in that it could provide not only demonstrative procedures but also axioms from which to work; and he set down appropriate rules of argument. His religious writings were published shortly after his death; many attempts have been made to reconstruct the apology which they encapsulate. It seems most likely that this would have fallen into two parts, the first setting out the wretchedness of humans without God, the second demonstrating the truth of Christianity and the felicity of the religious life. Humans are portrayed in Augustinian terms as corrupt, vapid creatures, prey to their passions and the delusions of imagination; but they are also shown to possess greatness through their reason and self-awareness, which can bring them to recognize that Christianity alone has represented their predicament accurately, and that they should turn to religion, even if initially they lack the instinctive faith which is the hallmark of the saved. In the 'wager' fragment, Pascal employs his mathematical insights to revivify an old apologetic argument (that it is wiser to bet on God existing rather than on his not existing) and to link it to an existential imperative (that we all are obliged to choose between these alternatives). The adroit interplay between scepticism, rationalism and faith of the first part is succeeded by a second part which argues the veracity of Christianity from Biblical interpretation, prophecies and miracles. Pascal concedes that this cannot carry absolute conviction; but he insists that the rejection of such arguments is caused not by man's rational powers but by his corrupt passions. Pascal's* Pensées *are written for the most part in terse aphoristic form; he aspired to a style that was so accessible that the reader would believe he was experiencing as his own the thoughts that he read. Although Pascal said at the end of his life that he considered his mathematical pursuits a quite separate enterprise from his religious writings, a common epistemology can be found in both, together with a scientific outlook which Pascal saw as superior to the philosophical alternatives of his day.*

1 Early life and mathematical works

Blaise Pascal was born in Clermont in Auvergne, the son of a government official who was also an enthusiast for the new mathematical learning. With his family, he moved to Paris in 1631, and stayed there until 1638, when his father was forced to flee because of his public opposition to an aspect of Richelieu's fiscal policy. Blaise was educated privately by his father, who wanted him to be fully conversant with Greek and Latin before introducing him to mathematics: but his prodigy son worked out for himself the principles of geometry as far as the thirty-second proposition of Book I of Euclid at the age of twelve. It was also during this Parisian period that he was able to attend the mathematical academy of Father Marin Mersenne who was actively engaged both in European scientific and philosophical circles and in the religious controversy surrounding the new scientific ideas, as Pascal himself was also to become engaged. It is unclear how well-grounded Pascal was in the classics and in traditional Aristotelian logic and physics, and whether his unconventional education contributed to the originality that he showed in his later career.

After his father had been pardoned by Cardinal de Richelieu for his dissent and given the office of royal tax commissioner for the province of Haute Normandie, Pascal went with him to Rouen in 1640; in the same year his first mathematical publication, the *Essai pour les Coniques* (Essay on conical sections), appeared. Two years later he invented a calculating machine, which he had originally conceived to help his father with his tax work; this remarkable achievement was far in advance of the industrial skills required to produce it, although various versions were made and demonstrated to scientific colleagues, prominent politicians and members of the aristocracy.

2 The debate over the vacuum

Between 1646 and 1648, Pascal became embroiled in the fierce European debate concerning the existence of the vacuum. Torricelli's experiment with a barometer, which involved placing a tube of mercury upside down in a bowl of mercury, had been made public in France by Mersenne in 1644, and had given rise to many competing interpretations. Nearly all of these had recourse to the notion of atmospheric pressure as an explanation, and there was general agreement that the space at the top of the tube contained some kind of rarefied and invisible matter, which was consistent with the Aristotelian adage *natura abhorret vacuum*. In 1647, Pascal published his *Expériences nouvelles touchant le vide (Experiments on the vacuum)*; this was the summary of a series of experiments he conducted with Pierre Petit, using variously sized and shaped tubes and different liquids. Through them he was able to determine the quantity of water and mercury that could be supported by air pressure and the size a siphon had to be in order to function. He also set out in this summary the reasons why there was no rarefied and invisible matter occupying the space above the column of liquid supported in the barometer, but did not feel able yet to affirm the existence of a vacuum. He was challenged in his conclusions by Father Étienne Noel, the Jesuit Rector of the Collège de Clermont in Paris and a proponent of traditional Aristotelian physics; Pascal set out in his reply what are now taken to be the basic principles governing the application of scientific judgment and method. At the same time, he wrote to his brother-in-law Florin Périer to ask him to undertake the experiment of carrying a barometer up a mountain (the Puy-de-Dôme), the results of which showed that the level in the column of mercury varied with height. Pascal confirmed this himself on a church tower in Paris, and published the findings in 1648 in his *Récit de la grande expérience de l'équilibre des liqueurs (Account of the great experiment on equilibrium in liquids)*; he concluded that experiment, not authority, governed physics, that his experiments had shown that nature has no horror of a vacuum, and that air pressure accounts for all the effects associated with said imaginary horror. These experimental writings played an important role in discrediting Aristotelian and scholastic scientific ideas (see Aristotle; Aristotelianism, medieval; Aristotelianism, Renaissance).

3 Pascal and Jansenism

Pascal's father suffered an accident in 1646, which brought him into contact with a priest sympathetic to the ideas of Cornelis Jansen (1585-1638), the bishop of Ypres. Pascal also encountered Jansenist ideas on grace and piety, and was deeply affected by them, as were other members of his family. After her father's death in 1651, Blaise's sister Jacqueline became a nun at the convent at Port-Royal, which was the centre of Jansenist doctrine and religious practice in France (see Port-Royal). Pascal opposed her vocation strongly, and indeed for two years thereafter led a life very different from hers, consorting with free-thinkers, gamblers and libertines of fashionable Parisian society; but on the night of 23 November 1654 he underwent a profound spiritual experience which altered his life irrevocably.

This 'nuit de feu' was such that Pascal sewed the record that he made of it at the time of the event itself as a permanent memento into his clothes, where it was found at his death. The document records an experience of conversion; not an intellectual experience, but one which persuaded Pascal of the superiority of instinctive belief. (This conviction was strengthened two years later, when his niece was cured miraculously at Port-Royal of an apparently incurable fistula.) As a result of his experience, Pascal went to Port-Royal-des-Champs for a two-week retreat in 1655. There he met Isaac Le Maistre de Saci, a Jansenist theologian, with whom he had a debate, an account of which was published in 1720 as *Entretien avec M. de Saci (A conversation with M. de Saci)*. This debate indicates not only that Pascal had conceived of an apology of the Christian religion in terms which would speak most powerfully to the very libertines and gamblers of the Parisian society which he had just forsaken, but also that he felt that one of the most powerful voices with which he had to contend was that of Michel de Montaigne, the gentleman philosopher who had championed the cause of scepticism in the later sixteenth century. It is also clear that he felt the need to reassure those who had been shaken in their faith by new scientific developments, especially those in astronomy. Among Pascal's immediate sources of inspiration was Antoine Arnauld, the leading Jansenist theologian and philosopher, who was at that time on the point of being condemned by the Sorbonne for his religious views. Together with Arnauld and Pierre Nicole, another prominent Jansenist, Pascal composed the *Lettres provinciales (Provincial letters)*, a series of eighteen letters published in 1656-7. These constitute a scathing attack on the moral and theological views of the Jesuits, who were the most vociferous opponents of both Arnauld and Jansenism. In this debate the Jesuits were somewhat unfairly represented as a religious faction which engaged in deliberate deception for political ends and sacrificed doctrine to morals, and the

Jansenists were for their part depicted as crypto-Calvinists whose interpretation of St Augustine was both erroneous and heretical. Pascal and his co-authors tried vigorously to rebut the charge of heresy levelled at Jansen's writings while still acknowledging the authority of the Church that as Roman Catholics they were bound to accept. As it transpired, the debate was won *de facto* by the Jesuits; the *Lettres provinciales* were placed on the Index of Forbidden Books in 1657, and the Jansenist movement itself was condemned by the Pope shortly after. But the wit of the letters and their dazzling display of satire and irony have ensured that the judgment of posterity has been accorded to Pascal's side, at least in literary terms. For all that, the school at Port-Royal was closed in 1661, and the remaining *solitaires* and nuns were forced to sign a document to mark their submission to the Roman Catholic Church; this prompted Pascal to write the *Écrit sur la signature du formulaire (Tract on the signing of the formulary)*, urging Port-Royalists not to sign. In it he reiterated the defence of Jansenism which is found in the *Lettres provinciales*, distinguishing between fact and faith or law in matters of religion. Councils, Fathers of the Church and popes are infallible on matters of faith, but not on matters of fact, and Pascal contends that the identification of Jansenism with heresy is a matter of fact, not law. The *Écrit* was never published because Nicole and Arnauld contradicted Pascal's advice. After a stormy altercation with them, Pascal renounced all further engagement in religious controversy. Instead he devoted his final months of life to the poor of the part of Paris in which he lived, not only making over all his worldly goods to them, but also organizing what was in effect the world's first omnibus service, which carried passengers from one part of Paris to another for a fixed fare. Throughout his short life, he had never enjoyed long periods of good health; he died on 19 August 1662 after a protracted and painful illness, and his final days were marked by his own deep piety and his desire to fulfil his religious duties to the last.

4 Works posthumously published

Although Pascal was well known to the European scientific community in his lifetime, few of his works were published. His last foray into the world of mathematics - the solution to a set of problems concerning the nature of the cycloid - was in fact circulated anonymously as a competition in 1658, although its author was sufficiently well-known for the Dutch mathematician and physicist Christiaan Huyghens (1629-95) to write to Pascal about it in the following year. After Pascal's death some mathematicians (including Leibniz) had access to his scientific papers, but these did not all appear in print until much later. Pascal's religious writings, however, were posthumously edited by his family and friends; the *Pensées* and other short works appeared in 1670, and the *Entretien avec M. de Saci* in 1728. The original edition of the *Pensées* was both an abridgment and a reworking of Pascal's papers, only part of which had been put in order by him; since the mid-nineteenth century various attempts have been made to reconstruct the manuscript as it was left by Pascal, culminating in Louis Lafuma's edition of 1952 which is now taken to be standard. More recently still Pol Ernst has been able not only to reconstruct the pages which were cut up by Pascal himself when he decided to arrange the fragments into thematic groups, but also to establish the date of composition of the major part of the project (1656-8). This recent scholarship has permitted a (somewhat conjectural) chronological ordering of the *Pensées* to be published and has opened up new possibilities for their interpretation.

5 Mathematical philosophy

Pascal himself said in a letter to Pierre Fermat written in 1660 that he felt that his religious writings had little connection with his scientific and mathematical work. His outlook, however, was deeply influenced by what he conceived to be a new way of looking at the world inspired by geometry, and most commentators would agree that all his writings are impregnated with it. He himself made strictly mathematical contributions to number theory, geometry and probability theory, but he also involved himself in the wider polemic about the status of science in his day. In his letter to Father Noel, he set out the prerequisites of sound scientific methodology, laid down the rules for making affirmative or negative scientific judgments (through axioms and apodictic demonstration), and for establishing or disproving hypotheses about the physical world, which in his view could never be more than provisional. In the same letter, Pascal referred to the rival claims of authority (in this case, the authority of Aristotle) and scientific demonstration; this topic is more fully developed in the *Préface sur le traité du vide (Preface to a treatise on the vacuum)* (1651?), in which Pascal shows that experiment and correct reasoning should govern the sciences, and that authority and historical example have no place in them. His view of science is very much a progressive one; as more and more experiments are undertaken with more sophisticated instruments, previously accepted hypotheses are supplanted by newer ones. Thus the hypothesis of occult qualities or powers,

which was postulated to explain what lies beyond sensory perception, and the Aristotelian distinction between act and potency, should be replaced if experimentation can show that they are inadequate according to Pascal's rules. Natural causation and phenomena are unchanging; human attempts to understand them are relative to the historical moment at which the attempts are made. In a striking image, Pascal refers to the successive generations of scientists as a single person in a perpetual state of existence and development. Thus, when we disagree with scientists of the past, we are not contradicting them, since by applying the principle of charity we would have to agree that we would have understood the world in their way had we lived in their times with their resources; and it follows also that they would have agreed with us today for the same reasons. (It is worth noting that Pascal is willing to believe that past scientists acted and wrote in good faith, whereas he refused to concede that his Jesuit opponents did so.)

De l'Esprit géométrique et de l'art de persuader (On the spirit of geometry and the art of persuasion) (1657-8?) is a yet more sophisticated presentation of the new scientific outlook. Pascal begins by conceding that definitions in geometry are nominal and not real, and that what are taken for axioms are intuitive perceptions which can neither be demonstrated nor reasonably be doubted. The four terms which he identifies in this way are number, space, movement and time. All share the property of being infinitely divisible and infinitely extensible. This insight is counter-intuitive to those who conceive knowledge as finite but, unless it can be grasped, then the geometric spirit itself cannot be comprehended. Pascal is not claiming that man's capacity for knowledge is unlimited; merely that the immediate information of his senses and his reason have to be transcended if scientific advances are to be made. Geometry emerges from this as superior to logic, in that it can both provide axioms and engage in demonstration, whereas logic can only do the latter.

The second part of the work is devoted to the thorny problem of persuasion; here the will comes into question as the path through which human assent to a given argument is to be obtained. Even here, however, a method or a set of rules are supplied for the correct conduct of an argument. Terms must be given clear definitions, axioms must be incontrovertible and must all be explicit, and conclusions should be checked by substituting definitions for the terms used. Pascal's discussion of scientific method is therefore distinct from Bacon's negative use of induction although, like Bacon, he conceives of science in evolutionary terms; nor does it evince Descartes' greater reliance on the resources of human reason; it harnesses the arguments of the sceptics, but escapes from their epistemological dilemma by positing intuitive truths which do not come to us from the exercise of our intellect (see Bacon, F. §§2-6; Descartes, R. §§2-3).

6 Theology and the human condition

In 1658, Pascal gave an account of his planned apology for the Christian religion to his friends at Port-Royal, which is probably the reason for his cutting up his sheets of reflections and notes and arranging them into bundles. It is far from certain, however, that all the fragments which survive were written as part of this one project, or that the project was anything like complete and fixed in Pascal's mind. Not only are sections of the text in dialogue, with none of the voices clearly identified, it also seems likely that the grammatical first person who appears in a number of other fragments does not refer in all cases to Pascal himself. Such interpretative problems have not deterred past editors from partial or total reconstructions of the apology. The Lafuma edition, which is less interventionist, begins with a section devoted to the proposed organization of the work, which makes its general character clear. In the first part, the human condition was to be described, and shown to be wretched; in the second, human felicity with God and the truth of the Christian religion were to be demonstrated. In a series of sections entitled 'vanity', 'misery', 'ennui', 'causes of effects', 'greatness', 'contradictions', 'distraction', 'philosophers', Pascal sets out a description in implicitly Augustinian terms of human experience of the world. The arbitrariness and injustice of human political institutions, the vapidity of human pastimes, the false notions of social hierarchy, and the wilful flight of humans from confronting the primordial questions of their existence are all memorably expressed, often in terse aphoristic form. Notable is the very low assessment of the moral nature of humanity, whose self is said to be hateful. Pascal then turns to the paradox that in the human's very wretchedness there lie the seeds of greatness. Although the passions and imagination pervert and oppress them, humans also possess reason and self-awareness, and even can attain to certain knowledge about their environment through their intuitive grasp of geometric axioms. Such intuition, which Pascal sites in the heart, is also where true faith in God is to be found; the function of his apology is to persuade his reader rationally that the Christian religion is true because its description of the human condition is accurate, but it cannot do more than predispose the reader to

receive the gratuitous divine gift of faith. In this sense it is a superfluous enterprise; and although in his *Écrits sur la Grâce (Writings on grace)* (1657-8?) he tries to come to terms with the Tridentine proposition that the just are able of themselves to obey the Commandments, Pascal seems to concede the inefficacy of instilling rational conviction alone at various points in the *Pensées*.

As he does elsewhere, Pascal here sets up powerful binary oppositions between philosophies and exploits their reciprocal failings and strengths. Scepticism is modest in its claims, yet impotent and negative; dogmatism (roughly, rationalistic neo-Stoicism) is presumptuous and yet has some purchase on the real world. Philosophy is therefore incapable both of knowing humanity and of taking action. Pascal finds a way beyond this impasse by exploiting his insight about the infinitely great and the infinitely small in a novel manner: humans are everything with respect to nothing, and nothing with respect to everything (God and the cosmos). They are also imbued with a desperate desire for certainty, and cannot suspend their judgment indefinitely, because they are subject to an existential imperative: ‘you must take on the bet, for you are in the game’ (Pascal 1670: 550 [L418]). This is the context of the famous wager argument, which had been used before Pascal by other apologists. Either God exists, or he does not: if human life is vain and wretched (as Pascal believes he has demonstrated), humans have nothing to lose by betting on the next life (that is submitting to the Christian religion), for they have lost nothing in the case of God’s nonexistence, and gained everything if he does exist. Some have seen this argument as purely rhetorical; others have accused it of being a case of *petitio principii* (the worthlessness of life is presupposed in the conclusion that we have nothing to lose in sacrificing the allegedly vain pleasures of this world); yet others see in it an ingenious example of decision theory *avant la lettre*. Whatever interpretation is given to it, it can be seen to be particularly apposite to the potential constituency of libertines and gamblers whom Pascal was intending to address.

Pascal’s apology is therefore not simply fideistic, postulating the two truths of faith and reason; it employs both faith and reason, as well as doubt, to achieve certainty. As one *pensée* has it ‘one must doubt in the right way, assert in the right way, and submit in the right way’ (1670: 523 [L170]). Descartes tried to demonstrate too much, and relied on his *cogito* to gain knowledge of an infinite and hence incomprehensible God; Montaigne doubted too much, and did not agonize enough about his passive acceptance of ignorance and hedonism; only Pascal (and his mentor St Augustine) used reason to affirm, to negate and to recognize its own limitations appropriately. In the second part of his apology, Pascal planned to use arguments from Biblical history, prophecies, miracles, and above all else the interpretation of Holy Writ to present the case for the truth of Christianity; but he conceded that such proofs were not absolutely convincing, although they were sufficient to secure the consent of those who read them free from the perverting effects of their own corrupt passions.

In the *Pensées*, as in the *Esprit géométrique*, Pascal is at pains to stress the importance of style. The great art, which he identified in Epictetus, in Montaigne’s essays as well as in his own writings, was to write in such a way that those reading would think that they could have written the text themselves. As he shrewdly put it: ‘it is not in Montaigne, but in me that I find all that I find in his text’ (1670: 591 [L689]). Knowledge has to be made desirable, and also to be made accessible; the writer is its undetectable mediator; truth, as he had asseverated in the letter to Father Noel, is itself not a historical or personal phenomenon. The fortunes of his own writings do not seem to bear this out. In the late seventeenth century, he was the champion of those who embraced Augustine’s gloomy vision of corrupt human nature; in the eighteenth century, he was reviled for the same reason by moralists of a more optimistic bent; in the twentieth century he was caused to doubt the existence of God in the early part, a Kierkegaardian existentialist in the middle, and is now appreciated as a rhetorician and precursor of probability theory. The sustained interest shown in his work is a testament to its linguistic brilliance, its brevity and its clear vision of an epistemology embracing both the seen and the unseen, the intuited and the perceived, and the natural and the supernatural, all grounded in an impressively coherent outlook derived from his particular conception of geometry.

Passmore, John Arthur (1914-)

John Passmore was born in New South Wales and studied at the University of Sydney. He taught there before moving to Otago in New Zealand and then to the Australian National University. He is perhaps best known for A Hundred Years of Philosophy which has been widely recognized as a major feat of philosophical scholarship. He has contributed widely to topics in the history of philosophy, philosophy of education, philosophy of science and philosophy of the environment. He is one of the pioneers of what has come to be called applied philosophy.

Passmore was born in Manly, New South Wales. He was an early student of the influential Scottish-born philosopher John Andersonat the University of Sydney. He taught at Sydney before going to the Chair of Philosophy at the University of Otago in 1950. In 1955 he moved to the Institute of Advanced Studies at the Australian National University where he was Reader and then Professor of Philosophy. He has held a number of senior visiting appointments in universities outside Australia and was Tanner Lecturer at Cambridge University in 1980.

For much of his career Passmore was something of a lone voice in Australian philosophy. His interests were more historical and applied than was usual in Australia in the 1950s and 1960s; indeed his work was probably better known during this period in Britain and America than in Australia. This changed with an increase in interest in the history of philosophy and especially in the contributions philosophers can make to issues of general concern that started in the 1970s, and many of his writings, particularly those on the philosophy of the environment, have become a focal point of discussion in Australia as well as overseas. He has an unusual ability to write argumentatively rigorous and philosophically sophisticated prose that readers not professionally involved in philosophy find challenging but not intimidating. In consequence his influence has extended well beyond philosophy departments. He has played an important role in showing the world at large how philosophers of an essentially analytical bent can make major contributions on subjects of general concern. He must be regarded as one of the pioneers of applied philosophy.

Passmore's best known book, especially among professional philosophers, is *A Hundred Years of Philosophy*, first published in 1957. It is widely recognized as a remarkable work of scholarship that displays an encyclopedic knowledge of the major philosophical movements of the preceding one hundred years combined with an intimidating understanding of their historical origins. It established his reputation in the history of philosophy. It has been a goldmine for teachers and students of philosophy, and a major first port of call for non-philosophers.

It is, however, his writings on the philosophy of the environment that have been the most influential in the sense of setting the agenda (see Environmental ethics; Green political philosophy). In *Man's Responsibility for Nature* he argues that we need as a matter of urgency to change our attitudes to nature, that we cannot go on living, as we have been, as predators on the biosphere. At the same time he argues vigorously against the view that we should see our present predicament as a sign that we should abandon the Western scientific and rationalist tradition and embrace some form of irrationalism or mysticism. The book is both an important contribution to environmental philosophy and an attack on the scientific irrationalism that is prevalent in some sections of the environment movement. In particular, he argues that the view that it is the Western tradition *per se* that is responsible for our present predicament is based on a misreading of and a selective attention to the complex historical facts. Rather, Passmore argues, we should use the tools that this tradition has provided us with to find our way out of our present predicament. A distinctive feature of the argument of the book, and indeed of much of Passmore's work, is the way it is set within a historical setting. He seeks to tell us how we got to where we are before telling us what we should do about it.

In *Philosophical Reasoning* a number of distinctive styles of reasoning in philosophy are identified and subjected to critical scrutiny. The book was published in the early 1960s, a time during which it was commonly claimed that these distinctive styles of argument, recently uncovered, served to dissolve many traditional philosophical problems. The enthusiasm with which philosophers embrace a new style of argumentation is not always matched by their readiness to examine its credentials, and this book played an important, if sobering, role.

Patañjali (*c*. 2nd century BC)

The grammarian Patañjali lived in the second century BC*, before the appearance of the classical systems of Indian philosophy. The aspects of his thought that we would call philosophical are concerned primarily with questions of meaning and meaning-bearers in language.*

1 Patañjali and philosophy

Patañjali is the author of the *Mahābhāṣya (Great Commentary)*, which comments on Pāṇini's famous grammar called *Aṣṭādhyāyī* (*c*. fourth century BC) and on Kātyāyana's *Vārttikas*; the latter have only survived as part of the *Mahābhāṣya (Great Commentary)* (*c*. second century BC). Patañjali is one of the few authors of early India whose approximate date is probably known. He lived around the middle of the second century BC in the north of India during the incursions into the country of the Graeco-Bactrian king Menander, to which he refers. This early date is confirmed by the absence of influence from the classical systems of Indian philosophy on his thought, with the possible exception of Sarvāstivāda Buddhism.

The *Mahābhāṣya* is not primarily a philosophical treatise. It addresses some philosophical questions in its introduction (whose title is *Paspaśāhnika*) while commenting upon certain grammatical rules (*sūtra*) of Pāṇini. Interestingly, Patañjali (who often sides in this respect with Kātyāyana) does not always share Pāṇini's point of view.

2 The linguistic units that have meaning

Rule 1.2.45 of Pāṇini's grammar states that 'what is meaningful, but is not verbal root or affix, is nominal stem' (*arthavad adhātur apratyayaḥ prātipadikam*). If we use the term 'stem' to refer to both verbal roots and nominal stems, this *sūtra* makes clear that for Pāṇini only stems and affixes really have meaning. Combinations of stems and affixes, that is, words and sentences, have at best meanings that are derived from those of the constituent stems and affixes. For Patañjali the situation is the exact opposite of this: words and sentences, not stems and affixes, are meaningful. This is clear from his discussion of rule 1.2.45 where he observes that this *sūtra* would assign the designation 'nominal stem' (*prātipadika*) to words and sentences. This contingency is avoided with the help of some far-fetched and unconvincing arguments. Next Patañjali turns to the question of how stems and affixes can be thought to have meaning, which he considers problematic, unlike Pāṇini. In Patañjali's opinion the nominal stem *vṛkṣa* on its own expresses no meaning. Cardona (1967-8) delineates the following solution offered by Patañjali: the method of concurrent occurrence of meaning and linguistic unit (*anvaya*) and absence of these two (*vyatireka*) shows that *vṛkṣa*, which is the common part of *vṛkṣas*, or 'one tree' and *vṛkṣau*, or 'two trees', must have the meaning, 'tree'. In this way, Patañjali derives the meaning of the stem *vṛkṣa* from the 'real' meanings 'one tree' and 'two trees'. The pair *pacati*, 'he cooks' and *paṭhati*, 'he recites', he similarly points out (*sūtra*1.3.1) allows us to assign a meaning to the common part -*ati*. Speaking generally, the meanings of stems and affixes are derived from the meanings of complete words.

Patañjali's deviation from Pāṇini is most easily explained by the hypothesis that he was influenced by the Sarvāstivāda Buddhists, who had reified phonemes and words (and perhaps sentences), but not stems and affixes, into existing 'real' elements (*dharma*). This is confirmed by the fact that Patañjali, too, accepts phonemes and words, but not stems and affixes, as independently (and eternally) existing entities. In connection with these independently existing phonemes and words, Patañjali uses several times the expression *sphoṭa*, which plays a major role in the discussions of later grammarians. Unlike them, Patañjali does not look upon the *sphoṭa* as a meaning-bearer, according to Joshi (1967). He speaks, for example, of the *sphoṭa* of individual phonemes. This *sphoṭa* is different from the sound (*dhvani*) which manifests it. The word or phoneme (*śabda*) is the *sphoṭa* and the sound is a property of the word or phoneme. If one person speaks slowly, another quickly, the *sphoṭa* is the same, only the manifesting sound is different (see Language, Indian theories of §§1, 3).

3 Do phonemes have meaning?

Although reticent with regard to the meaningfulness of stems and affixes, Patañjali pays great attention in his second chapter (*āhnika*) to the question of whether individual phonemes have meaning. He argues that certain stems and affixes consist of just one phoneme. The verbal root *i*, for example, means 'go'. Certain words which are

identical but for one phoneme, express different meanings: *kūpa* means ‘well’, *sūpa* ‘soup’, *yūpa* ‘sacrificial post’. Also, the removal of one phoneme can change the meaning: *vṛkṣa* means ‘tree’, *ṛkṣa* ‘bear’. Finally, if phonemes had no meaning, collections of phonemes could have no meaning either; one hundred blind people cannot see more than what one blind person can see. Patañjali subsequently rejects these arguments. Sounds normally have no meaning, because they can be modified, elided, or change position in a grammatical derivation. Since only collections of phonemes have meaning, nothing can be concluded from sets of similar words like *kūpa*, *sūpa* and *yūpa*, nor indeed from the pair *vṛkṣa* and *ṛkṣa*. Collections of phonemes can have features which the constituent phonemes do not possess: a chariot, too, can perform functions which its parts cannot.

4 The meaning of a word

What is the meaning of a word according to Patañjali? In the second *āhnika* four kinds of words are distinguished according to what they refer to: words that refer to a genus (*jātiśabda*), those that refer to a quality (*guṇaśabda*), those that refer to an action (*kriyāśabda*) and arbitrary proper nouns (*yadṛcchāśabda*). The first three of these clearly designate nouns, adjectives and verbs respectively. But in the first *āhnika* Patañjali enumerates (twice over) the following four classes of words: nominal words (*nāman*), verbs (*ākhyāta*), preverbs (*upasarga*) and particles (*nipāta*). This enumeration is taken from Yāska’s *Nirukta* (*c*. third century BC [1967: I.1]), where the meanings of these different types of words are elaborately discussed. Nominal words (nouns and adjectives), for example, are there described as ‘having *entity* as their predominant notion’ (*sattvapradhāna*), verbs as ‘having *being* as their predominant notion’ (*bhāvapradhāna*) (Kahrs 1986: 117). Patañjali was probably aware of the meanings assigned to words there.

Elsewhere (especially in *sūtra* 1.2.64) Patañjali distinguishes two possible meanings of words: the form (*ākṛti*) or the individual object (*dravya*). The former of these two positions is associated with the name of Vājapyāyana. Vyāḍi, on the other hand, held that words denote individual objects. Here, it seems, the discussion concerns itself with nouns primarily. In fact, there is reason to believe that for Patañjali ‘form’ (*ākṛti*) and ‘genus’ (*jāti*) were synonyms. Patañjali himself held that both form and individual object constitute the meaning of words.

Paternalism

Restriction of people's liberty of action is paternalistic when it is imposed for the good of those whose liberty is restricted and against their will. The argument in favour of paternalism is that, if one can prevent people from harming themselves, there is no reason not to do so. Versions of the ethical creed of liberalism tend to oppose paternalism. One argument is that as a practical matter the policy of permitting paternalism tends to do more harm than good in the long run, or at least less good than a strict refusal to countenance paternalism would achieve. Another argument appeals to a right of autonomy which paternalism is held to violate whether or not its consequences on the whole are undesirable. Paternalist advocacy can be 'hard' or 'soft'; soft paternalism is the doctrine that paternalism can only be justifiable when the individual action that is being restricted was not chosen in a substantially voluntary way.

1 The concept of paternalism

One behaves paternalistically if one treats an adult as though one were a parent dealing with a child. One's behaviour shows concern for the welfare of the person and a presumption that one's judgment about what will promote it is superior. The paradigm of paternalism, and the focus of most philosophical discussion of it, is restriction of people's liberty against their will for their own good.

Whether a restriction of liberty is paternalistic or not depends on its rationale. If most people want a law requiring that they wear seat-belts when riding in cars for their own protection, and we enact a law in order to cater to this desire, enforcing this policy restricts people's liberty, but not against their will. In its application to the minority who do not want to be under this requirement, the law is still not paternalistic - though it may be unfair - if its rationale is administrative convenience and not the aim of restricting people's freedom against their will for their own good.

2 Utilitarianism for and against paternalism

The case for paternalism is simple. If we can prevent people from harming themselves, why not do it? According to act utilitarianism, one ought always to do whatever would produce the most good (utility) for people (and perhaps other sentient creatures) (see Utilitarianism). Whenever restricting someone's liberty to prevent harm to that very person is the utility-maximizing act, then act utilitarianism requires us to do it. Utilitarianism imposes stricter requirements of benevolence than most people accept (see Help and beneficence). One might hold that the better the cost-to-benefit ratio of a paternalistic act, the more obligatory the performance of the act. Or one might hold that so long as a paternalist imposition would do more good than harm, it is permissible even if not morally required.

In *On Liberty* (1859), a classic statement of a liberal utilitarian antipaternalism, John Stuart Mill does not dispute the theoretical possibility that in particular circumstances restricting someone's liberty for their own good might be the best thing to do from a utilitarian standpoint. Mill nevertheless proposes a liberty principle, which asserts that in modern societies the liberty of a sane and cognitively competent adult should never be restricted except to prevent harm to other persons who do not consent to this involvement (see Mill, J.S. §12).

Among its several implications, Mill's liberty principle forbids paternalistic restriction of liberty. Mill argues that we should adhere to this principle because in the long run, as a practical matter, rigid adherence to this rule would better promote utility than any alternative policy including the more flexible rule that forbids paternalism except in those particular situations in which paternalism happens to be utility-maximizing. Given that humans, including the humans who would administer any paternalist rule, are imperfectly rational, imperfectly well-informed, and not always disposed to be moral, the attempt by society to follow the liberty principle would produce more human happiness than any other course.

Mill's pragmatic defence of the liberty principle appeals to the likelihood that individuals will know their own interests better than those who are tempted to impose paternalistically on them, so such restriction will often be misguided. He also sketches a broad account of human nature and of what is needed to promote human fulfilment. According to Mill, humans vary in their natures. Given this diversity, no one or a few modes of life will be suitable for everyone. Moreover, our individual natures are not transparent to ourselves. One must learn about one's own

individual nature in order to develop a reasonable plan of life. This process of individual self-discovery requires wide freedom to try out different modes of life and to observe the results of other people's experiments in living. As we learn about the possibilities inherent in our nature, we come to value some above others, and work to mould our characters so as to conform to a self-chosen ideal. In short, Mill believes we need to develop our individuality to have a good chance of happiness, and to develop individuality we need wide individual freedom.

Leaving aside the merits of Mill's bold psychological speculation, one notes that his argument from the need for individuality to a rule against paternalism is incomplete. Even if we need wide freedom to develop our individual natures, it might well be best if people are stopped from the most disastrous and stupid self-harming activities.

A second criticism of Mill's argument is that, even if his claim that refraining from paternalistic imposition would maximize utility in the long run were correct, it might still be morally desirable to embrace some paternalism to achieve fair distribution of utility. A strict no-paternalism policy will tend to produce good outcomes for prudent individuals who are skilled at making and executing personal decisions and less good outcomes for individuals whose prudential skills are poor. On the average the imprudent bad choosers will be living worse lives. Even if strict no-paternalism happened to be utility-maximizing, instituting some paternalism might be better for worse-off persons, and required by fairness norms, especially if one thinks that imprudence is often nonblameworthy.

3 The right to autonomy; hard and soft paternalism

A more direct argument for the rejection of paternalism would dispense with utilitarian calculations and simply posit a moral right to live one's own life as one chooses so long as one does not thereby harm others in wrongful ways. On this view each individual has a right to autonomy, a right to govern their own life. Neither other individuals nor society as a whole has the authority to restrict an individual's liberty so long as the person's conduct is at worst self-harming and does not violate the rights of others.

The right to autonomy just described is stronger than a right against paternalistic imposition, because restriction of someone's liberty of action is paternalistic only if done for the sake of the individual who is coerced (or others who consent voluntarily to share involvement in the activity), and one might restrict an individual's liberty when it is conceded that the individual is not wrongfully harming others, in circumstances such that restricting the person's liberty would benefit others.

The right to autonomy as so far characterized is little more than a slogan pending further clarification of what its components might mean. One idea that calls for clarification is the idea that I have the right to act according to my own choices in self-affecting matters. But some restriction of people's choices does not seem to involve any overriding of their considered judgment and will. If Gertrude drinks a cup of poison, thinking it is harmless wine, she does not choose to bring about her death voluntarily. If Ulysses is driven temporarily insane by the Sirens' song, restricting his liberty for his own good is not really done against his will, because the will that chooses on the basis of insane impulse is not his authentic will. The ideal of voluntary choice encompasses many disparate disabilities. The more one chooses voluntarily, the more one is not choosing in ignorance of material matters of fact, not choosing on the basis of an error in reasoning, not choosing under conditions that tend to cloud judgment, not choosing under threat of coercion or duress, not insane or lacking basic cognitive capacities, and so on. Writers have distinguished 'hard' and 'soft' advocacy of paternalism. Soft paternalism is the doctrine that paternalism can only be justifiable when the individual choice that is restricted fails to be substantially voluntary - to meet a threshold level of voluntariness. The hard paternalist position holds that paternalism can be justifiable even if the individual action that is restricted is substantially voluntarily chosen.

One might interpret the right of autonomy as prohibiting paternalistic restriction of liberty only if the individual choice that is restricted is substantially voluntary. Or one might adopt a sliding scale: the more voluntary the choice, the stronger the moral presumption against the legitimacy of paternalism. Other views are possible - for example, one might hold that the legitimacy of paternalism depends both on the degree of voluntariness of the choice that is to be restricted and on the severity and danger of self-harm which the chosen conduct threatens to bring about.

Patočka, Jan (1907-77)

*Patočka was a Czech philosopher, one of the last pupils of Husserl. From the mid 1930s he developed his own approach to philosophical problems of the life-world (*Lebenswelt*), its structures and human activities in it. After 1945 he expanded this theme to incorporate other phenomenological problems (movement, freedom, aesthetics). He also paid much attention to the history of philosophy since antiquity, particularly to Comenius. After 1972, when the Communist system deprived him of his academic position, he elaborated his philosophical concept of History in his 'Heretical Essays'. He was one of the authors of the political manifesto of the Czechoslovak political opposition, Charter 77, and his name became a symbol of moral resistance against totalitarian power.*

Patočka (born in Turnov, died in Prague) was a leading Czech philosopher of the twentieth century. After studying in Prague, Paris, Berlin and Freiburg, where he was a pupil of Husserl and Heidegger, he was awarded a Chair at Prague's Charles University as a result of his work *The life-world as a philosophical problem*. At this time he was secretary of the Czech-German group 'Cercle philosophique de Prague', and helped with the preparation of the International Philsophical Congress in Prague in 1934. During the Nazi occupation of Czechoslovakia (1939-45) universities were closed, and Patočka taught at a grammar school. After the war he returned to his university post but was dismissed for political reasons in 1949. He could, however, carry on his scientific work at the Academy of Sciences. At the time of the 'Prague Spring' (1968) he was reinstated at the University, but had to leave again in 1972. Subsequently, he organized illegal lectures and seminars, joined an opposition movement against the Communist regime and was co-author of the political manifesto, Charter 77. When he suddenly died after a series of police interrogations, his name became a symbol of moral resistance against totalitarian power, and of the fight for human rights.

Patočka follows the humanistic tradition of Czech thinking which starts with the founder of the Czech Reformation, Jan Hus, and his predecessors; he demands that philosophy should lead us from daily banality to full humanity. The philosopher is defined as one who has broken through the cycle of demand and consumption, who has elevated themselves above the world towards permanent values. Patočka links this mission of philosophy with an analysis of the crisis of modern rationality as described by Husserl. He seeks a way out of this crisis in the adherence to the life-world. This is the elementary world of humans, the pre-reflexive and prescientific world, but a world in which we can find the sense of our existence. Patočka does not understand this world in the sense of Husserl's transcendental subjectivity, but emphasizes its existential, ontological dimension, its autonomy and non-reducibility; he calls his approach 'a subjective phenomenology'. Humans control this world (and are controlled by it) by three different kinds of movement. First, the movement of acceptance, 'taking root', that is finding one's place in the world. Second, the movement of defence, the labour which keeps humans going in the world and secures their basic needs. Third, the movement of truth, transcendence, which humans use to step over matters given to them directly and with which they reach the world as a whole. Patočka was alone for a long time in developing the problems of the life-world. Only from the end of the 1950s were these problems dealt with more frequently in phenomenological writing. The international philosophical public first saw the fundamentals of Patočka's work in the 1976 French translation of his *The life-world as a philosophical problem*.

Another of Patočka's contributions to phenomenological problems concerns the philosophy of history. Husserl himself only touched on the question of history in his *Crisis in the European Sciences*, where he understands the problem of history in a narrow sense as the problem of the *notion* of the life-world. He does not take this problem as far as a concrete human life in the world, in society and in history (see Husserl, E. §12). Patočka attempted to do that in his work *Heretical Essays on the Philosophy of History*, written in the early 1970s at a time when he was not allowed to publish in his home country. This book, which outlined the foundations for Patočka's political activities, was therefore distributed illegally. (A French translation appeared in 1981, with a prologue by Ricoeur and an epilogue by Jakobson.) According to Patočka, history starts when people realize the problems of their hitherto matter-of-course life, when the meaning of their life as understood until then is shattered and they discover the possibility of a free life. This happened first in the Greek *polis*, origin of politics, history and philosophy, whose inter-relationship became the legacy of European people. The loss of the previous purpose of life was the beginning of a search for a deeper, freer and more demanding purpose, but not for the final purpose - history is not something conclusive. This is why one cannot take the attitude of a disinterested spectator towards history; each

has to feel responsible for it. From this follows the need to influence general matters and at the same time to 'look after one's soul'. Care for the soul is unthinkable without care for the commune. Human activity is a prerequisite for the movement of history.

Throughout his life, Patočka also studied the history of philosophy, understanding it as a stimulus for live philosophizing. In this spirit he wrote studies of Socrates, Plato, Aristotle and numerous works on Comenius. It is mainly to Patočka's credit that Comenius ceased to be seen as just a brilliant educator: Patočka proved that Comenius's ideas on education were based on an original philosophical concept, so that his outstanding position in the history of European philosophy has also to be recognized.

Patristic philosophy

*Early Christian writers used terminology and ideas drawn from Graeco-Roman philosophical literature in their theological writings, and some early Christians also engaged in more formal philosophical reflection. The term 'patristic philosophy' covers all of these activities by the 'fathers' (*patres*) of the Church. The literature of nascent Christianity thus contains many concepts drawn from Graeco-Roman philosophy, and this early use of classical ideas by prominent Christians provided an authoritative sanction for subsequent philosophical discussion and elaboration.*

Early Christians were drawn to philosophy for many reasons. Philosophy held a pre-eminent place in the culture of the late Hellenistic and Roman world. Its schools provided training in logical rigour, systematic accounts of the cosmos and directions on how to lead a good and happy life. While philosophical movements of the period, such as Neoplatonism or Stoicism, varied widely in their doctrines, most presented accounts of reality that included some representation of the divine. These rationally articulated accounts established the theological and ethical discourse of Graeco-Roman culture. As such, philosophy had a natural appeal to Hellenistic Jewish and early Christian thinkers. It provided a ready language in which to refine ideas about the God of the ancient Hebrew scriptures, and to elaborate the trinitarian God of Christianity. It also helped to bring conceptual coherence to the ideas found in the scriptures of both religions. Finally, it provided the common intellectual discourse that those communities required in order to present their central tenets to the majority culture of the Roman empire.

To a considerable extent, the notion of 'philosophy' suggested to the ancients a way of life as much as an intellectual discipline. This too drew Christians to the teachings of the philosophers. While there were doctrines and prescriptions of behaviour specific to the major schools, philosophers in general tended to advocate an ethically reflective and usually rather ascetic life, one which conjoined intellectual with moral discipline. This ethical austerity was prized by early Christians as an allied phenomenon within Graeco-Roman culture to which they could appeal in debates about the character of their new movement. The tacit validation that philosophy offered to the Christian movement was thus multifaceted, and, while it was sometimes thought to be associated with unacceptable aspects of pagan religious culture, philosophy provided some educated Christians with a subtle social warrant for their new life and beliefs.

It should be noted that ancient Christianity was itself a complex movement. Like Graeco-Roman philosophy, Christianity included a broad spectrum of beliefs and practices. Thus those early Christians who developed their beliefs with reference to philosophy endorsed a wide range of metaphysical and ethical doctrines, ranging from materialism to extreme transcendentalism, from asceticism to spiritual libertinism. Yet, while diversity is evident, it is also true that the Christian movement came to develop a rough set of central beliefs and some early forms of community organization associated with those beliefs. This incipient 'orthodoxy' came to value some sorts of philosophy, especially Platonism, which seemed best suited to its theological agenda. This tacit alliance with Platonism was fraught with ambiguity and uncertainty, and it was never a reciprocal relationship. Nonetheless, in the second and third centuries a type of Christian philosophical theology emerged which owed much to the Platonic school and became increasingly dominant among orthodox Christian authors. It was this trajectory that defined the character of patristic philosophy.

Early Christian thought had its origins in Hellenistic Judaism, and its initial character was defined by the dominant patterns of that tradition. This early phase extended through the first half of the second century AD, as Christianity began to define its distinctive themes associated with the nature and historical mission of Jesus Christ. Throughout the second century, Christianity became increasingly a movement made up of gentile converts; some of these new members had educations that had included philosophy and a few were even trained as philosophers. Thus Christian thought began to show increased contact with the Graeco-Roman philosophical schools, a trend no doubt reinforced by the critical need for Christians - as a proscribed religious minority - to defend their theology, ritual practices and ethics in the face of cultural and legal hostility.

This so-called 'age of the apologists' lasted throughout the second and third centuries, until Christianity began to enjoy toleration early in the fourth century. However, it would be a mistake to consider Christian philosophical thought in that period as primarily directed towards the surrounding pagan society. In many respects philosophy, as the intellectual discourse of Graeco-Roman culture, offered gentile Christians a means to clarify, articulate and

assimilate the tenets of their new faith. This process of intellectual appropriation appears to have been of considerable personal importance to many Graeco-Roman converts. Christian philosophical theology helped them to recover ideas familiar from their school training and to find unfamiliar concepts defended with the rigour much prized within Graeco-Roman culture.

After Christianity became a licit religion in the fourth century, philosophical activity among Christians expanded. The task of theological self-articulation became increasingly significant as Christianity grew in the fourth and fifth centuries towards majority status within the Empire, with imperial support. In this later period the range and sophistication of Christian thought increased significantly, due in part to the influence of pagan Neoplatonism, a movement that included a number of the finest philosophers active since the classical period of Plato and Aristotle. Later patristic philosophy had a defining influence upon medieval Christian thought through such figures as Augustine and Dionysius the pseudo-Areopagite, establishing both the conceptual foundations and the authoritative warrant for the scholasticism of the Latin West and Greek East.

1 Influences

Judaism in the time of Jesus of Nazareth was the heir of centuries of reflection on the unique existence of God, some of which was partly conditioned by Greek philosophical speculation. The book of Proverbs in the Old Testament emphasizes the one God who is the source of all wisdom and who produced the world (Proverbs 3: 19; 8: 22-31). Here wisdom begins to appear in a hypostatized role, as a quasi-independent power which serves to instantiate and express the hidden purposes of God (Proverbs 8: 1-31). Wisdom is the first product of God, and as such is a mediator between God and humanity. In the *Wisdom of Solomon*, an intertestamental work written between 100 BC and AD 50, wisdom (*sophia*) is presented as a distinct power that orders the cosmos and reveals the moral structure that conforms to that divine production. Wisdom is praised for her power and exalted as the source of prophecy and human sanctity. These texts indicate a characteristic aspect of Hellenistic Jewish theology: exaltation of a single, universal God in cosmological and ethical terms combined with discussion of a secondary principle that serves as an instrument of divine production and moral revelation.

Philo of Alexandria, the pre-eminent Jewish philosopher of the period, was preoccupied with the articulation of biblical theology in terms of Greek philosophy. His treatises, written in Greek, had a defining influence on early Christian philosophy, both in method and content. The works of Philo present philosophical interpretations of the Hebrew Bible, which he read in a Greek translation (the Septuagint), using strategies of allegorical exegesis. His philosophical sources are characteristic of the Hellenistic period, a mixture of Stoic, Peripatetic, Pythagorean and Platonic conceptions in which the transcendentalism of the Pythagoreans and Platonists was predominant (see Platonism, Early and Middle; Peripatetics; Pythagoreanism; Stoicism). For Philo, the patriarchs, especially Moses, were philosophers; it was to Moses that God revealed the transcendent archetypes upon which creation was based. These paradigms - understood as Platonic forms - constituted both the inherent patterns of order within the cosmos and the transcendent powers which generated it. Collectively, they were described as the Logos or divine Word, the ‘place’ of the forms. Philo used numerous ways to express this notion of an intermediate level of reality; sometimes the Logos seems to be only an aspect of God, in his role of relating to his products, but at other times the Logos seems to be a secondary entity that emerges from God and is used as an instrument to structure the cosmos. Other names or figures are also used, such as Wisdom (as we have seen), Goodness or Sovereignty; each represents an independent aspect of the divine nature. These ‘principles’ or ‘powers’, however understood ontologically, function to mediate between the primordial aspect of God and the cosmos that emerged from him.

One aspect of Philo’s portrayal of God bears particular mention: his unwillingness at times to attribute descriptive terms to God, particularly those that suggest direct divine interaction with the cosmos. Here Philo seems not only to be building upon traditional Hebraic reluctance to employ a proper name for God, but also to be drawing upon Pythagorean and Platonic theology, which proscribed ascribing predicates to the ‘One’ or the ‘Good’. Powers such as Logos or Sophia appear as the pre-eminent representations of the hidden and unsearchable divine nature, the self-revelation of God in metaphysical terms. But He Who Is, the God of Exodus, remained hidden in his august transcendence. This model of philosophical theology, with its interplay between a largely ineffable God and intermediate divine representations, would have a major effect on subsequent Christian thought, suggesting a philosophical approach to reflecting on the nature of Christ (see God, concepts of).

The use of philosophical discourse in Hellenistic Jewish thought was part of a natural strategy of cultural

association, drawing Judaism into discussion with ideas that were well-established within its host society. But it represents as well an internal development away from more archaic anthropomorphic conceptions of God, a development common to the Mediterranean religions of the age. Philo's use of Graeco-Roman philosophy is an important instance of this anti-anthropomorphism. God is a remote divine being who, if he can be described at all, can be approximated by metaphysical terms such as 'One', 'Good' or 'Monad'. It was God's Logos or Sophia that acted as a demiurge to craft the cosmos and now controls the world according to God's good purposes.

2 Beginnings of Christian thought

Some of this thinking seems to have influenced the earliest Christian writers of the New Testament, especially Paul and John. Although there is no firm consensus among scholars on the precise details of this relation, some patterns are evident. In Romans 1: 19-21, creation is understood to be an act of divine revelation, universal in its scope. The one God must, for Paul, be more than the guardian of an individual people, but also the source and judge of all humanity (Romans 3). The one God directs all things providentially for the good. This idea of a single God whose universal revelation is creation can also be found in speeches attributed to Paul in Acts (14 and 17).

It is in explaining the nature of Jesus Christ that the letters attributed to Paul clearly evince aspects of Hellenistic Jewish wisdom theology. Colossians 1: 15-23 presents a pre-existent cosmic power who is the image of the invisible God and the entity first born from God. This being is the creative power, by whom all things came into being, whether earthly or heavenly. The cosmic Christ is thus ontologically central: 'all things were created by him, and for him, and he is before all things, and by him all things consist' (Colossians 1: 16-17). In Paul's theology it is this power that manifested itself in Jesus of Nazareth, who died on the cross in order to reconcile a fallen world to himself and thus to God. The exact import of such Pauline passages is difficult to assess, since their conceptual background can only be approximately recovered. The same is true of the splendid prologue to the Gospel of St John. Similar prepositional language is used there to indicate the causal and ontological significance of a unique entity. The Word or Logos was *with* God in the beginning and serves as the power *through* which all things were made. As such, the Logos is the principle of life and light, and a power manifested historically in the human person of Jesus of Nazareth. This iteration of a cosmic mediator in Pauline and Johannine texts became the basis of subsequent Christian ontology, although these interpretations would differ significantly.

In the early second century, we find evidence of a developing consensus among Christian authors about God's metaphysical properties. Ignatius, the early second-century bishop of Antioch, writes about Christ as a timeless, invisible, intangible, and impassible being who shed these characteristics in order to become human (*Epistle to Polycarp* 3: 2). In the mid-century *Apology* of Aristides, God is presented in philosophical terms as the unmoved mover, the ruler of the universe and an eternal being without beginning or end. As such, he is understood to be ungenerated, immutable, free from need or defect, immobile and exempt from partition or division. These metaphysical epithets were commonplace among pagan philosophers of the period, and their adoption by early Christian apologists suggests a common theological discourse to which the new movement was making explicit appeal (see God, concepts of).

The effort to articulate a first principle which was transcendent of the cosmos led many Graeco-Roman thinkers, particularly Pythagoreans and Platonists, to reject the ascription of many characteristics, such as mutability or mobility, to the deity. This 'negative theology' came sometimes to regard all predication to be inadequate, so that even notions such as perfection or immateriality seemed too restrictive (see Negative theology). This tendency - mediated through Jewish thought - is also to be found in second-century Christian thinkers, especially some loosely classed as 'gnostics', who believed that they possessed a special, higher knowledge (*gnosis*) of the ineffable God beyond the divinity revealed in the sacred scriptures (see Gnosticism). An example is Basilides, a gnostic teacher of the mid-second century, who adopted a line of thinking whose roots go back at least as far as Plato's Academy. He held that the first principle could not be described by analogy with anything within the cosmos, but was best thought of as 'without being'. This completely transcendent power cannot be understood from the perspective of the universe; indeed, even calling it 'ineffable' is suspect. Similar views are common among other second- and third-century gnostic Christian authors. Their theology usually contrasted a hidden first principle, to whom special access is required, with lesser but misguided divine powers, whose presence is more easily attested.

However, this transcendentalism was not the whole story in early Christian thought. Some Christians were

influenced by more materialistic Roman philosophical schools, and their thinking was sharply opposed to the strongly transcendentalist tendencies of the gnostics. Perhaps the best example is Tertullian, a Roman jurist who converted to Christianity and campaigned vigorously for an understanding of the scriptures which was corporealistic, along the lines of Stoicism and Roman medical theory. For Tertullian, God was a spirit *sui generis*, a being understood in an attenuated materialist way, as a force which was invisible but nonetheless part of the cosmos. Similarly, the human soul was a corporeal entity, transmitted in the act of conception and immortal only through divine intervention. Such thinking was constructed in opposition to the developing transcendentalism of the early Christian Platonists, and it underscores the fact that the scriptural record could well have been read through a very different philosophical prism. But, as it happened, Tertullian's materialistic theology became a dead end, as the affinity of Platonism and Christianity was successfully argued by Christian philosophers in the second century.

3 Early Christian Platonism

By the latter half of the second century AD, Christianity had become largely a gentile movement, with a complex political and cultural relationship to the Roman Empire. Philosophical reflection was an important component in the developing self-articulation of the movement. A good example is the second-century *Apology* of Athenagoras of Athens, who wrote eloquently to the Stoic Emperor Marcus Aurelius in defence of Christianity, arguing that in rejecting the pagan gods Christians were not atheists, but believers in a single first principle. This cultural polemic is supported by his philosophical treatise *On the Resurrection of the Dead*. Here he addresses the composite nature of the human person, and argues that the unity of body and soul must be restored after death through resurrection of the body if human beings are to fulfil the eternal destiny intended by their divine creator. These arguments have an Aristotelian flavour, indicating a sophisticated and flexible use of philosophical sources. Similarly the three books entitled *Ad Autolycum* by Theophilos of Antioch, written about AD 181, contain arguments cast in philosophical terms. Written by a Christian convert to a pagan friend, these treatises argue for the uncreated nature of God, who is immutable but creates through his Logos. This Word exists both within God and also as the external expression of God through which he expressed himself in the act of creation.

The most important of these early apologists was Justin Martyr, who was executed *circa* AD 165. Justin was trained as a philosopher, having tried the Stoic, Peripatetic, Pythagorean and Platonic schools before converting to Christianity. His extant writings include two *Apologies* and a *Dialogue with Trypho the Jew*. Justin spent time as an itinerant Christian philosopher and even wore the philosopher's cloak (*pallium*) before settling in Rome, where he founded a school. Justin's approach to Graeco-Roman philosophical and religious culture was complex. In his view, the ancient Greek thinkers had access to the Old Testament and learned from it. Moreover, the divine Logos, the Wisdom of God, was the rational foundation of both the universe and the human soul, so that a natural knowledge of God was accessible to pagan philosophers. For Justin, all who think and act according to reason do so by participating in the Logos. Abraham and Socrates were Christians in anticipation of Christ, the incarnate Logos. Justin thus used philosophy to present a broad defence of Christianity, one that not only employed specific arguments in defence of scriptural conceptions, but also discovered a wide-ranging historical scheme to conjoin both the Hebraic and Hellenic cultures within Christianity.

The central locus of Christian philosophical activity in the second century was Alexandria, a major cultural centre of the Empire. There we find a Christian school, a succession of Christian teachers and pupils whose activities seem to parallel that of pagan philosophers. Clement of Alexandria is the first of the Alexandrian Christian teachers about whom much is known, although he himself refers to several earlier figures, especially Pantaenus, a former Stoic. Clement was probably a convert; he was born in mid-century and died around AD 215.

His principal work, the *Stromateis (Miscellanies)*, is a compendium of ethical and theological observations on a wide range of topics. Clement's goal seems to have been the presentation of a broadly educated, cultured form of Christianity. Its adepts would be Christian gnostics; unlike others who claimed that name, they would be both members of the developing orthodox movement and truly enlightened thinkers. Their life was described by Clement in ethical terms drawn from Stoic, Platonic and Aristotelian literature, characterized by an effort to approximate the stability and impassibility of God's own being. Pagan philosophy was significant in Clement's view since it represented a parallel phenomenon, the result of the illumination of the Greeks by the divine Logos. This notion of the natural knowledge of God allowed Christians like Clement to treat philosophy as an anticipation

of Christianity, a path to a common fund of knowledge completed by the revelations found in the Jewish and Christian scriptures.

In reading scripture, Clement owed much to Philo’s allegorical method of exegesis. Through the latter, Clement was able to discover the gnostic, or deeper, meaning of texts whose origins and character seemed remote from cultured Graeco-Roman sensibilities. This more advanced reading, grounded in philosophy, separated the simple believer from the mature or gnostic Christian, whose wisdom was enriched by this joint foundation in natural and revealed truth. Clement’s capacious model of Christian wisdom, with its compatibilist understanding of the Graeco-Roman and Hebraic traditions, helped to establish an enduring Christian approach to philosophy and, more generally, to the classical heritage.

Clement’s Logos theology had another feature which followed Philo’s thought, namely his emphasis on the unknowability of God. This ‘negative’ theology was, as we have seen, an important theological strategy in the period. The concept of a primordial but uncharacterizable godhead revealed through a lower power or aspect was widely accepted by Pythagoreans, Platonists and many heterodox Christian gnostics. But Clement, like Philo before him, put this negative theology to a positive use. The ultimate God was understood as beyond finite description, having no conceptually adequate predicates; but God was not thereby cut off from the world, nor was the cosmos at the mercy of ignorant or malevolent intermediate powers. For Clement, this hidden God, alluded to by the philosophers, was made manifest in his Word, the Logos, the transcendent power which produced the world and then became present in the person of Jesus of Nazareth. It is this fine balance between the hidden and the apparent that characterizes Clement’s theology, setting his views into sharp contrast both with heterodox gnosticism and with more affirmative or literalist approaches to theology within early Christianity. This difference, between apophatic theology (the theology of *apophasis* or denial) and kataphatic theology (that of *kataphasis* or assertion) thus came to the surface within orthodox Christianity through the catechetical school at Alexandria.

4 Origen

The greatest theologian in the era before Christianity’s legitimation in the fourth century was Origen of Alexandria, a product of the Alexandrian Christian school. Origen was born into a Christian family about AD 185; his father was martyred, a fate which Origen himself also suffered, dying subsequent to torture in the Decian persecution around AD 254-5. An intense reader of scripture from his youth, Origen studied both in Christian schools and in the pagan philosophical school of Ammonius Saccas, the teacher of Plotinus. Origen’s many writings encompass apologetics (for example, *Contra Celsum (Against Celsus)*), biblical commentary and systematic treatises (*De principiis (On First Principles)*). Much has been lost, although the substantial works that remain give ample evidence of vast scriptural erudition combined with a bold command of contemporary Platonic thought. Origen may fairly be said to be the most innovative Christian thinker of the pre-Nicene era, the most brilliant and important Christian intellectual before Augustine.

Unlike Clement, Origen generally avoided negative theology, perhaps because of its popularity among the heterodox gnostic thinkers whom he opposed. His theology focused upon the self-diffusion of God, a single divinity that produced a finite and intelligible image. This image - the Word - is the collective world of the Platonic intelligibles and the foundation of the lower, created cosmos. The Word is eternally generated by the Father, so that God is eternally productive of his perfect image. As such, the Logos appears to hold an intermediate status in the structure of reality, the link between God and the cosmos. Matter was also attributed by Origen to God, who was thus the only foundation of reality.

Origen also made human freedom central. Souls were seen as rational beings created with free choice. On Origen’s Platonic exegesis of Genesis, souls that turned away from God descended to lower levels of reality. Freedom of choice produced psychic precipitation, the falling of rational souls into their present corporeal state. This primordial loss of perfection resulted in a cosmic system of distinct worlds. Each degree of reality was attuned to the level of the soul’s descent. Souls only slightly separated from God could continue to engage in everlasting contemplation; Origen identified these with the stars. Others were entombed in human bodies and are subject to death. The demons are souls who chose the most extreme removal from God. Thus the cosmos was the direct manifestation of a fundamentally moral phenomenon; reality is the expression of the ethical disposition of its inhabitants. No other Christian philosopher in the patristic period linked moral freedom so directly with ontology.

Since evil is, in this theory, the direct result of the soul's choice, the natural evils of our world and mortality itself are epiphenomena of moral evil (see Evil, problem of). Death is thus punitive, and suffering educative. The cosmos is a vast penal colony designed for the rehabilitation of souls. Origen seems moreover to have held that all souls would eventually be successfully reformed. This universalism presents cosmic history as a providential process which will eventuate in a restoration of perfection, 'that God may be all in all'. Whether this reformation of souls precludes for Origen an additional, subsequent misuse of freedom is unclear. One corollary of Origen's universalism, that the devil would be saved, was not lost on his contemporaries; it contributed to the controversy which surrounded Origen's thought throughout late antiquity.

5 Later patristic philosophy: Gregory of Nyssa, Marius Victorinus, Ambrose

In AD 313, the imperial Edict of Milan initiated a new era of religious legitimacy for Christianity; shortly thereafter, the great ecumenical Council of Nicaea (AD 324-5) began the process of defining orthodoxy with imperial support. Christian philosophy was influenced by both events. No longer was there a need for political polemics in defence of the faith, although the effort to present Christianity to educated pagans continued unabated. Now, internal efforts to define and explain the doctrines of orthodoxy came to the fore.

These developments are particularly evident in the works of three Cappadocian bishops, Gregory Nazianzen (*circa* AD 330-90), Basil of Caesarea and Gregory of Nyssa (*circa* AD 330-90). Of these, the most philosophically acute was Gregory of Nyssa, whose theology is much influenced by Origen and by post-Plotinian Platonism (see Neoplatonism). Unlike Origen, Gregory did not ground his thought exclusively on a model of free will and psychic precipitation. Rather, divine creation is the dominant image and the soul but a creature conditioned by God's providential intention. That eternal plan involved materiality and the body. Thus the fall constituted a desecration of human nature, but it did not generate the mingling of soul with body. The misery of human life can be overcome only by restoration of our original state through God's intervention, through Christ. Philosophy can guide the soul to recognition of its condition, but the soul can be saved only by God's activity. Philosophy alone can never be sufficient for salvation.

Gregory's thought put a renewed emphasis on the conceptual transcendence of God, so that the divine Father was presented along Plotinian lines as being beyond all predicative descriptions. In Gregory's case, this view was based upon a sharp recognition of divine infinity. The created soul has, as its future course, the eternal process of the contemplation of God's infinitude; unification of the human soul with the one God can never be wholly consummated.

Gregory of Nyssa and the other Cappadocians are evidence of a great emergence of Christian Platonism in the Greek world of the late fourth century. This same post-Nicene flowering of philosophical theology also occurred in the western portions of the Empire. Here the influence of the Greek philosophical schools was somewhat less direct, in part because of linguistic difficulties, but it was still felt. Marius Victorinus was a Roman rhetorician much influenced by the works of the Plotinian school; he translated some of these into Latin and wrote treatises with a pronounced Neoplatonic influence in defence of Nicene orthodoxy. For Victorinus, Platonism seemed a conceptual resource and philosophical ally of Christian orthodoxy. This is also true to an extent of Ambrose, the great fourth-century bishop of Milan, who was concerned not only with re-drafting Christian theology in a Platonic idiom accessible to cultured pagans, but also with presenting Christian asceticism and theology as a successful rival to Platonic philosophy. His strategy had internal resonance within Christianity as well, allowing orthodoxy to assert its superiority to Arianism, Manicheism and other forms of Christianity (see Manicheism). His greatest success was the conversion (from Manicheism) of the North African rhetorician Augustine, whom he baptized in AD 387. It was the preaching of Ambrose, together with his treatises, that led Augustine to study 'the books of the Platonists' which Marius Victorinus had translated. This proved a spiritually volatile mixture, sending Augustine into an orthodox Christian trajectory and a life of asceticism.

6 Later patristic philosophy: Augustine, Boethius, Pseudo-Dionysius

Like Gregory of Nyssa and Ambrose, Augustine was determined to construct a coherent Christian theology which could stand as a compelling alternative to the still active and prestigious pagan tradition. It is well to remember that Julian the Apostate, the recidivist emperor who sought to restore a paganism through the revitalization of polytheistic cult and Neoplatonic theology, ruled during Augustine's youth (AD 361-3). Augustine's thought might

well be considered as a fresh response to the same set of desiderata as had moved Gregory and Ambrose: problems internal to Christianity and external ideas which were hostile to orthodoxy. Perhaps because he read little Greek and had an informal philosophical education, Augustine's thought is less a Christianized Platonism than it is a systematic development of Christian theology, using Platonic epistemology and metaphysics. Often Augustine seems intent on answering classical philosophical questions in novel, Christian ways.

Nowhere is this clearer than in the *Confessiones (Confessions)*, where Augustine carefully asserts his own personal success at Plotinian contemplation in the vision at Ostia, only to conclude that pagan philosophy, while providing the soul with epistemic access to God, was inadequate as a means of assuring continuing salvific association with God. Augustine presents this theme as an autobiographical refutation both of Manichean materialism, now confounded by the soul's transcendental vision through contemplation, and Platonism, found wanting in its prideful over-estimation of the soul's natural proximity to the eternal and the divine. These opponents are the background to the brilliantly original account of memory and time in Books X and XI of the *Confessiones*, where the phenomenology of the fallen, embodied, and temporally constrained soul is explored. This account of the human soul constructing a lapsarian self and so constituting time as the medium of its collective anxiety and loss had a decided impact on the development of the introspective consciousness of the West and on the framing of a philosophical account of Genesis.

Throughout the vast corpus of his later writings, Augustine frequently makes use of philosophical notions, usually in contexts whose primary focus is theological. In the *De civitate Dei (City of God)*, however, he returns to the question of the value of philosophy, especially Platonism. In this sustained argument, he makes plain his admiration for the intellectual utility of philosophy, while rejecting the philosophers' pretence to salvific efficacy and excoriating their continuing acceptance of polytheistic cult. It is interesting to note that Augustine views Platonism as a natural approximation to Christianity, achieved through reason but without the benefit of revelation. Yet the Platonists were, in the end, spiritually incoherent, accepting a first principle, the Good or One, while countenancing polytheistic worship.

While Augustine was in many respects a *sui generis* thinker with a penchant for original reflection on philosophical topics, there were other Christian thinkers in late antiquity whose works were more clearly bound by philosophical conventions. Boethius is an outstanding example. An active member of the Roman senatorial circle during the Ostrogothic period in Italy, Boethius undertook the revival of technical philosophy at a time of its marked decline in the western provinces. He translated and commented on some of Aristotle's logical works, and wrote a series of five theological treatises on the Christological debates of his time. Most important for medieval and renaissance readers, he completed the *De consolatione philosophiae (Consolation of Philosophy)*, a protreptical work on the value of the philosophic life, while a political prisoner before his execution. In most respects, Boethius was a conventional Christian Platonist, although the Christian element can be found only in his theological works (see Platonism, medieval). His efforts to articulate and defend the congruity of divine foreknowledge and human freedom were critical to later medieval scholasticism, as were his commentaries on Aristotle. His pupil Cassiodorus continued aspects of the encyclopedic legacy of Boethius, concentrating his efforts on articulating the seven traditional liberal arts (grammar, dialectic, rhetoric, arithmetic, geometry, music and astronomy). He also wrote a treatise on the soul, arguing that it is transcendent of materiality, but distinct from God in its capacity for evil. As is the case with his teacher Boethius, Cassiodorus is significant primarily for his role in transmitting classical philosophy to the medieval age (see Encyclopedists).

At about the same time (early sixth century) in the Greek East there surfaced a collection of treatises under the name of Dionysius the Areopagite (St Paul's Athenian convert in Acts 17). The identity of the actual author has been the subject of extended speculation and remains undetermined, although the works came to be accepted as genuine in both the Byzantine East and later in the Carolingian West (see Pseudo-Dionysius). These treatises represent the high-water mark of compatibilism between Christianity and late Platonism. They centre on the absolute predicative transcendence of God. The soul must grasp the total darkness of divinity as well as the vast manifestation of its hidden nature in the cosmos that emerged from it. The whole of reality is a theophany, an expression of the One who cannot be known *per se*. The levels of reality that are manifest to us constitute grades of being, each part of a pattern of divine self-presentation and return. The concept of God, while undefinable, is not privative or nugatory but can be partially understood as characterizing the source of reality.

This theology represents a Christian redaction of the pagan Platonism of the fifth century. While assuredly Christian in its theological terminology, its basic ontology is intelligible only when read against the metaphysics of the pagan Neoplatonists. This was one possible line for Christian intellectual development. However, there were others who resisted such assimilation. Chief among them was John Philoponus, who was active in the Greek East during the first half of the sixth century. Philoponus was sharply opposed to pagan Neoplatonism, especially that of Proclus. He criticized Aristotelian and Neoplatonic claims about the eternity of the cosmos, and favoured a model of temporal creation. Even if the world were beginningless, it must be seen as a contingent system that depended for its existence upon a transcendent source. In his view, the eternalism of the pagan cosmologists occluded this central metaphysical point (see Eternity of the world, medieval views of). Moreover, the commitment of many pagan Platonists to a theory of necessary cosmic emanation from the One further confused the issue. In consequence, Philoponus attempted to clarify the fundamental ontological dependence of a contingent cosmos upon its divine creator. He is a representative of a vigorous Christian philosophical movement in late antiquity which sought to sharpen the lines of conceptual demarcation between Christianity and pagan Platonism, while using common methods of philosophical argumentation to achieve that end.

The closing of the pagan Platonic academy in Athens was ordered by the Emperor Justinian in 529. Subsequently philosophy continued in a variety of Christian philosophical schools, each committed to different, rival theologies, including monophysites, Chalcedonians and Nestorians. It was on this foundation that later Byzantine Christian philosophy and early Islamic philosophy were able to develop, transmitting the thought of both the classical and the patristic traditions into the medieval period.

Patrizi da Cherso, Francesco (1529-97)

*Francesco Patrizi was an Italian humanist and anti-Aristotelian who took up a newly-founded chair of Platonic philosophy at Ferrara in 1578, the first such chair in Europe. Through his various writings he contributed to poetic theory, rhetoric, and historiography, as well as to military history and hydraulics. His two most influential works were his Discussiones Peripateticae (1581) and his Nova de universis philosophia (New Philosophy of Universes) (1591). Patrizi cast doubt on the authenticity of many of the works attributed to Aristotle, and argued that Aristotle's philosophy was incompatible with Christianity. He believed it should be replaced with his own synthesis of Platonism, Neoplatonism, and Hermeticism (or Hermetism). Patrizi saw light as the basic metaphysical principle, and interpreted the universe in terms of the diffusion of light (*lumen*) from God, the primary light (*prima lux*). His most influential doctrine concerned space, which he argued to be infinite, three-dimensional, and distinct from the bodies it contained.*

1 Life and works

Francesco Patrizi (Franciscus Patritius) was born in Cherso, near Trieste. He studied in Venice and Ingolstadt, before going to Padua where he studied and taught private pupils for a number of years (1547-54). It was at this leading Aristotelian institution that he was introduced to Marsilio Ficino's *Theologia platonica (Platonic Theology)* (see Ficino §3), and became a Platonist. He spent some years away from the university, serving as secretary and administrator to various Venetian noblemen, and travelling extensively in France, Spain and Cyprus (where he perfected his knowledge of Greek). His return to the academic world marked the belated institutional recognition of Platonic philosophy. Shortly after Francesco de'Vieri (Verino) had begun teaching Platonic philosophy at Pisa in 1576, Patrizi took up a newly-founded chair of Platonic philosophy at Ferrara in 1578. In 1592 he was called to Rome by Pope Clement VIII and became professor of Platonic philosophy at the Sapienza. He still held this post at his death, despite ecclesiastical censure of his writings by the Roman Congregation of the Index, which ordered changes in his *Nova de universis philosophia (New Philosophy of Universes)*.

Patrizi's humanist and literary interests are shown in his works on poetry, rhetoric and history. He wrote poetry himself, one of his earliest writings was a discourse on types of poetic inspiration (*Discorso della diversità dei furori poetici*) (1553), and he later entered into a dispute with the poet Torquato Tasso about poetics. In his *Della poetica* (1586) he attacked the Aristotelian theory of poetry as mere imitation, and appealed to the marvellous as an aesthetic category (see Aristotle §29). The poet, who is 'maker of the marvellous', operates on the soul, putting it in tune with cosmic harmony. His views about the relationship between words and things also appear in his earlier work on rhetoric (*Della retorica*) (1562), where he claimed that search for rhetorical ornamentation had corrupted the original Adamic language which gave direct access to things (see Language, Renaissance philosophy of §2). In his work on history (*Della historia*) (1560), which had a great influence on later historiography, he attacked Ciceronian orthodoxy (see Cicero §2). He wanted to separate history from rhetoric, seeing it as an autonomous discipline with its own intellectual justification based on a grasp of causes and effects.

His other works included discussions of love, unpublished during his lifetime, in which he blended Neoplatonism with a naturalistic materialism. In another vein entirely, he wrote on military history, and was also the author of treatises on hydraulics, stemming from the conflict between Ferrara and Bologna over the silting of the river Po. Surviving correspondence shows his links with various intellectual circles.

His two most important works were the *Discussiones peripateticae* (*Discussionum peripateticarum tomi quattuor*) where we find his main attack on Aristotelianism, and the *Nova de universis philosophia* which presents his light-metaphysics and his philosophy of nature.

2 Anti-Aristotelianism

The prime source for Patrizi's attack on Aristotle is his *Discussiones peripateticae* published at Basle in 1581, though the first volume had been issued separately at Venice in 1571. This volume contained a biography of Aristotle which highlighted his personal shortcomings, such as stealing the ideas of his predecessors, and a history of Peripatetic philosophy. The three additional books discussed Aristotle's sources, the discord between Plato and Aristotle, and the defects of particular Aristotelian doctrines. Patrizi cast doubt on the authenticity of many of the

works attributed to Aristotle, and he foreshadowed modern commentators by arguing that Aristotle's *Metaphysics* was a series of fragmentary treatments of diverse topics rather than an integrated whole (see Aristotle §11).

Patrizi's main philosophical quarrel with Aristotle was that his philosophy was incompatible with Christianity, especially with respect to the providence and omnipotence of God. In his Dedicatory Epistle to *Nova de universis philosophia*, he blamed the study of Aristotle for the fact that 'Common men laugh indiscriminately at Philosophers with this saying, which is now a commonplace: this man is a philosopher, he does not believe in God' (Henry 1979: 559-60). The remedy for this situation was to be found in Patrizi's own philosophical synthesis of Platonism, Neoplatonism and Hermeticism (also known as Hermetism).

In order to understand Patrizi's synthesis, we must recognize his belief, taken from Ficino (see Ficino, M. §2), in an ancient theology (*prisca theologia*) handed down to sixteenth-century thinkers by a long and continuous tradition which began with Moses or even Noah, and which had the work of Plato as its ancient culmination. Both Plato himself, whom Patrizi presented as a genuinely systematic thinker, and the various works of the Hermetic tradition, were fitted into a Neoplatonic framework (see Neoplatonism).

Patrizi's attachment to non-Aristotelian sources is shown by his textual work. He translated John Philoponus' commentary on Aristotle's *Metaphysics* (1583) (see Philoponus §2) and Proclus' *Elements of Theology and Physics* (1583) (see Proclus §§2, 4, 9). One of the works he appended to his *Nova de universis philosophia* was his Latin translation of the *Theology of Aristotle*, a ninth-century Arabic compilation of extracts from Plotinus (§4) which Patrizi described as 'the mystic philosophy of the Egyptians dictated by Plato and taken down by Aristotle'. He also added an edition and Latin translations of the Greek *Corpus Hermeticum* and some other Hermetica, including the Latin *Asclepius*, all probably dating from between AD 100 and 300, as well as the Chaldaean Oracles, a work of the second century AD, which he attributed to Zoroaster (see Chaldaean Oracles). Contemporaries such as Teodoro Angelucci in his *Exercitationes* (1585) were already beginning to cast doubt on the historicity of the *Corpus Hermeticum*, when viewed as the work of the mythical Egyptian sage, Hermes Trismegistus, and as part of the *prisca theologia* handed on by Orpheus to the ancient Greeks, but Patrizi insisted on its authenticity and importance. In his Dedicatory Epistle he wrote: 'Surely Hermes' little book on piety and philosophy contains more philosophy than all of Aristotle's work' (Henry 1979: 553). He also claimed that Hermes was a little earlier than Moses, and had spoken more clearly of the Trinity (see Hermetism).

3 Light-metaphysics

Patrizi's main philosophical work, *Nova de universis philosophia* (Ferrara, 1591; Venice, 1593), is divided into four parts. Part One is called 'Panaugia' (all-splendour), a word borrowed from Philo Judaeus (see Philo of Alexandria). In the Platonic tradition, light had always been seen as a symbol of goodness and as the closest analogy to God in the physical world, and had early been turned into a metaphysical or ontological principle. Patrizi presented God as the primary light (*prima lux*), who produces light (*lumen*), first in his Son, then in all other incorporeal creatures. Finally, God produces all corporeal creatures via the diffusion of light in space. The roots of Patrizi's view can be found, not just in Plotinus and Proclus, but also in the medieval Jewish philosopher Ibn Gabirol and the Christian Robert Grosseteste (§3) (see Illumination).

Part Two is called 'Panarchia' (all-principle) and discusses the first principles that stem from God, who is One but who is also called the One-all. The highest principles are unity, essence, life and intelligence. The four lowest principles are nature, quality (see Ficino, M. §3), form and body. The intermediate principle is soul, which is midway between spirit and matter. In his discussion of this hierarchy of being, Patrizi was mainly concerned with the higher principles and the nature of God.

Part Three is called 'Pampsychia' (all-soul), and discusses all types of soul, from the irrational souls of plants to the world soul which animates the entire cosmos.

The fourth part is called 'Pancosmia' (all-world), and it is here that we find Patrizi's views on mathematics and natural science.

4 Philosophy of nature

Patrizi's view of space, which he called a 'corporeal incorporeal', is fundamental to his philosophy of nature.

Space has to be corporeal because it is extended or three-dimensional; it has to be incorporeal because it lacks both resistance and density, and can serve as a container for fully corporeal things. A similar analysis can be applied to light, which Patrizi also called a ‘corporeal incorporeal’; both space and light can then be seen as borderline entities between the realms of matter and spirit. Indeed, the analysis can be extended to soul, which also falls between the realms of matter and spirit (see §3), because soul is diffused throughout the physical world without itself being a physical thing.

Patrizi argued that space is prior to ordinary corporeal objects both metaphysically and temporally, and that it is a condition of the existence of other things. He was clearly influenced here by Plato’s *Timaeus* (see Plato §16), but his presentation was strengthened by his systematic, principled, rejection of Aristotle’s conclusions about place. Aristotle was confused because he had no notion of an incorporeal corporeal and did not see that what distinguishes space from body is not merely dimensionality but resistance.

Patrizi’s theory of space led him to new views of the void. Most notably, he called for an actually infinite void outside the physical world. Betraying some confusion (since an infinite space will have no centre), he added that it must be round, with the rotating earth as its centre. He also accepted an inter-particulate void, made of the naturally existing spaces between corpuscular bodies. Finally, like Telesio, he took stock arguments about the possibility of a naturally occurring intra-mundane void or vacuum, and used them against Aristotle’s denial of such a vacuum. He included reference to empirical data such as the operation of bellows and water clocks and what happens to closed containers of frozen water, but no actual experiment seems to have been involved. Theoretical reasoning predominated, and he did not really go beyond knowledge already available from ancient and Arabic sources. Both here and in his general discussion of space, Patrizi can be seen as preparing the way for modern science, but his role should not be overemphasized.

Another part of Patrizi’s philosophy of nature involved replacing Aristotle’s four basic qualities, hot, cold, wet and dry, with the four principles space, light (*lumen*), heat and *fluor* (fluidity, flux), which combine to form a hierarchy of mixed bodies. Particularly important here is the claim that *fluor* offers resistance to *lumen*. A corollary of this list of basic principles which were not hard or solid, was Patrizi’s claim that the heavens were fluid, and that the heavenly bodies were not fixed in hard, solid spheres as had commonly been thought. It is important to note that while Patrizi’s contemporary Tycho Brahe had astronomical arguments for the same view, Patrizi’s arguments were basically metaphysical.

A cautious assessment is also appropriate when one considers Patrizi’s praise of mathematics, especially geometry, for this seems more closely linked with his belief in an intelligible world and ideal forms than with any belief that mathematics could provide a tool for developing philosophy or for explaining the physical world.

Patrizi seems to have been more influential than the other so-called philosophers of nature, Bruno, Campanella and Telesio, and he was widely read in the seventeenth century. His theory of light was attacked by Mersenne (§3), while his views on space may have been handed on to Newton (§4) through the Cambridge Platonist, Henry More (§5), as well as Gassendi (§4).

Paul of Venice (1369/72-1429)

Like other teachers in fifteenth-century Italian universities, Paul of Venice focused on logic and natural philosophy in an undergraduate programme directed toward the education of medical students. Despite Paul's theological training and important position in the order of Augustinian friars, nearly all his works are non-theological. His prolific writings popularized the achievements of Oxford logic and Parisian physics in a framework derived from Aristotle and Averroes. As a philosopher he is best known for his Averroist position on the human soul, and for his moderate realism with respect to universals.

Paul of Venice (Paolo Nicoletti Veneto, born Udine 1369/1372, died Padua 1429) was active in three spheres. As an Augustinian friar, he served as Provincial of his Order. As a diplomat, he served as an ambassador of the Venetian Republic to Germany, Hungary and Poland. His most important career, however, was as a university teacher and author of textbooks. He taught briefly at various Italian universities, but his most constant association was with the University of Padua. He studied at the Augustinian *studium* in Padua both before and after his theological studies in Oxford (1390-3), and he taught at the University itself for many years. His academic concerns are reflected in the nature and number of his writings.

By far the most popular of all his works was the early *Logica parva*, which survives in over eighty manuscripts and was still being printed at the end of the sixteenth century. It shows the clear influence of his stay in England, for it takes the form of the textbooks then in use at Oxford and Cambridge. It begins with a tract called *Summule*, which summarizes standard medieval material on terms, propositions and arguments, and then offers a series of short treatments of supposition theory, consequences, the proof of terms, obligations and insolubles (see Logic, medieval). Paul uses sophismata, or puzzle-cases, to illuminate logical points, a standard technique in English logic texts. One of his less popular logic texts, the *Sophismata*, is entirely devoted to such puzzles, and they also form a large part of his *Logica magna*. The latter work, immensely long, was little read in Paul's time, but in the twentieth century a good deal of attention has been paid to it because it summarizes much of the logical work of the second half of the fourteenth century. Here as elsewhere, Paul often copied his sources word for word, and his own contribution was largely limited to modifying or expanding the views of others. Thus his solution to the problem of insolubles, which differs from the one he gives in the *Logica parva*, is a modification of Roger Swyneshed's solution (see Language, medieval theories of; Oxford Calculators).

The most popular of Paul's logic works after the *Logica parva* is a commentary on Aristotle's *Posterior Analytics* which, as a discussion of scientific reasoning, supplements his equally popular *Summa philosophie naturalis (Summa of Natural Philosophy)*. Each of these works survives in over fifty manuscripts and a number of printed editions. The *Summa* begins with a discussion of physics, and ends with short treatises on the soul and on metaphysics. In the latter, Paul uses material on the latitudes of forms drawn from the Oxford Calculators and the Parisian John of Ripa to explain the hierarchy of being. He argued that, contrary to the traditional theological view, God is not properly regarded as the measure of creatures since he is infinitely distant from them. Instead, finite things are ordered in the hierarchy of being in accordance with their distance from the bottom of the hierarchy, the zero grade of being.

One of Paul's chief philosophical concerns was the nature of universals, an issue he discussed in various places, including the *Summa philosophie naturalis (Summa of Natural Philosophy)*. His intention was to reconcile the 'modern' view, that knowledge begins with the cognition of singulars, with a realist view of universals that he saw as more consonant with Aristotle and Averroes (see Ibn Rushd). He argued that universals have real existence independent of the work of the intellect, but that their existence apart from singular things is only potential. His realist view of universals affected his attitude to Aristotle's categories, which he saw as reflecting the ontological structure of reality, and it is noteworthy that a large part of the discussion of metaphysics in the *Summa* is devoted to the categories (see Universals).

Another of Paul's concerns in the *Summa* was the nature of the human soul. He adopted the Averroist thesis that the possible intellect is one for all human beings, but argued that this one soul was individuated by becoming the substantial form of individual human beings. As a result, my knowledge can indeed be different from your knowledge. Only in his later commentary on Aristotle's *De anima* (the *Scriptum super libros De anima*) did Paul

worry about the compatibility of what he took to be the correct interpretation of Aristotle and Averroes with Christian doctrine. This commentary also reveals that Paul had changed his mind about the agent intellect. In the *Summa* he argued that it was the same as the possible intellect, but now he argued that it was to be identified with God. A further feature of Paul's Averroism was his acceptance of the thesis that the sensitive soul which we have in common with animals and the intellective soul which characterizes human beings are two separate souls (see Averroism).

The tension in Paul's works between the positions of Aristotle and Averroes and the rather different results of fourteenth-century Oxford and Paris is well illustrated by his changing position on impetus theory. In his *Summa*, he gave an account of projectile motion in terms of the impetus the projected object receives from its projector, a doctrine that he took largely from the Parisians John Buridan and Albert of Saxony. In his commentary on Aristotle's *Physics*, which was written in 1409, he reverted to the Aristotelian view that natural motion depends on the continued activity of a mover (see Natural philosophy, medieval). Despite Paul's often-changing opinions and his frequent lack of originality, his work was very influential in Italy during much of the fifteenth and sixteenth centuries.

Pecham, John (*c.*1230-92)

John Pecham, an English Franciscan, taught at Paris and Oxford, and died as Archbishop of Canterbury. His philosophical career represents a concentrated effort to defend the traditional views of Augustine and Anselm (among other theologians) against what was perceived as a growing tendency toward heterodox Aristotelianism, exemplified in such doctrines as the eternity of the world, a single intellect for all humankind and a divinity that had no knowledge of individual beings.

Born in Patcham in Sussex, England, Pecham was educated at the Benedictine monastery at Lewes and joined the Franciscans at Oxford during the 1250s. After continuing his education at Oxford, he was sent to Paris in the 1260s to complete his theological studies and in 1270 became regent master in Paris in the Franciscan chair of theology. Sometime after 1271 he returned to Oxford, where he became the Franciscan regent master of theology. He held that position until 1275, when he was elected minister provincial of the Franciscans in England, and in 1277 he was appointed lecturer to the papal curia. In 1279 he was named Archbishop of Canterbury, an office he held until his death.

As a student in the late 1260s, Pecham had undoubtedly heard the sermons of Bonaventure, who had alerted his listeners to the growing threat of unorthodox Aristotelianism. If Pecham was not directly involved in compiling the list of thirteen errors condemned in 1270 by Etienne Tempier, Bishop of Paris, he certainly would have agreed that the condemned propositions were erroneous. Together with William de la Mare, Pecham was one of the first Franciscans to oppose Thomas Aquinas, whose opinions were viewed as compromising Christian doctrine and too deferential to Aristotle and Averroes (see Ibn Rushd). This tendency continued in the followers of Pecham, namely Matthew of Aquasparta, Roger Marston, Bartholomew of Bologna, William of Falagar and, later, Vital du Four.

A true follower of Bonaventure, Pecham shows a fundamental allegiance to Augustine while accommodating the philosophy of Aristotle where possible. In the critically edited texts of the surviving works, Pecham shows little interest in logic or metaphysics. His writings reveal a preoccupation with the theory of knowledge, philosophical psychology, natural philosophy and science. In his theory of knowledge, Pecham supported Augustinian divine illumination with regard to first principles, claiming that the human intellect needed the ‘eternal reasons’ for the certitude of intellectual and moral first principles, although not for their contents (see Augustinianism). In contract to Aquinas, Pecham held that the human (as well as the angelic and divine) intellect had a direct knowledge of singulars. According to Aquinas’ interpretation of the Aristotelian thesis that the senses know the singular and the intellect the universal, the intellect must reflect on phantasms, products of the imagination, which receives its images from the senses, and then abstract the universal from the phantasms. In response, Pecham argues that the intellect abstracts either knowingly or unknowingly. If knowingly, then it had direct knowledge of the singular in the first place; if unknowingly, then how can it be called intellectual knowledge at all?

In addition to a set of disputed questions on the soul (*Quaestiones de anima*), Pecham also wrote a treatise on the soul (*Tractatus de anima*). In the former, he dismisses traducianism, which would have the human soul come from the divine substance, or from the bodies of the parents, or develop from a sensitive soul. Nor were all human souls created at the beginning of time, as Origen had held. Rather, each soul is created directly by God and infused into the body. Pecham vigorously defends the immortality of the soul, claiming that this can be demonstrated by seven irrefutable arguments (see Soul, nature and immortality of the). At the same time, he is opposed to multiple souls in the human being. There is only one (intellective) human soul, which, however, encapsulates the vegetative and sensitive functions as grades of a single intellectual ‘form’. He strenuously attacks as heretical Averroes’ denial that each human being had its own rational soul. Such an opinion jeopardized immortality and rendered the statement ‘I understand’ impossible, as Aquinas had pointed out.

The powers of the soul, though multiple, are not really distinct from one another or from the soul. The vegetative grade of the form is distinguished into nutritive, augmentative and generative. The sensitive grade has motive and apprehensive powers, the latter being distinguished into external (the five senses) and internal powers, the latter including the ‘common sense’, the imagination, the estimative (determining what is friendly or hostile) and the memory. The intellectual soul likewise has apprehensive and motive powers, the apprehensive being the agent intellect, the ‘possible’ intellect and the intellectual memory. The rational appetite or will comprises concupiscible

and irascible powers whereby it seeks the good and flees the harmful, powers which it shares with the sensitive grade. Freedom is not a separate power of the will; nevertheless, the will is so free that it can withhold consent in the face of the dictates of the (practical) intellect. This virtual containment of the various powers in the one intellectual soul anticipates, it would seem, the formal distinction of Duns Scotus.

In natural philosophy, Pecham opposes Aquinas on several issues. In Aristotle's view, every composite substance was made up of matter and form. Aquinas had held that prime matter, as the basis for substantial change, was pure potentiality. Pecham held that it was a positive identity, essentially and really distinct, so that by his divine power God could create prime matter distinct from any form whatever (*Quodlibeta quatuor* IV q.1). Aquinas likewise had held that there was but one substantial form in the human being uniting the soul to the body. Pecham responded with his theory of multiple grades, vegetative and sensitive, which persisted as (substantial) components of the human composite (*Quodlibeta quatuor* IV q.25). Thus the bodily, vegetative and sensitive 'forms' are not successively 'corrupted out' by the advent of the higher forms, as Aquinas would have it, but remain as grades of the higher form. Pecham may have been the first to introduce the grades theory as a refinement of 'tri-animism' or the plurality of substantial forms. While his treatise on this subject is apparently lost (Douie 1952: 280 n. 2), the salient points of his theory undoubtedly survive in his faithful disciple Roger Marston's *Quodlibet* II q. 22 (see Natural philosophy, medieval). Pecham likewise rejected Aquinas' view on the eternity of the world. The latter held that although *de facto* the world was created in time and there is nothing theologically or philosophically repugnant to the world's being created from all eternity (Brady 1974; Bukowski 1979). Like Bonaventure, Pecham believed that creation from all eternity was fundamentally contradictory (see Eternity of the world, medieval views of).

Pecham wrote a treatise on optics as well as a textbook on optics, the *Perspectiva communis*, and also a treatise on the spheres, a set of four disputed questions on the stars and a tract on mystical numbers (*De numeris misticis*). In addition he wrote numerous treatises on Franciscan spirituality (Brady 1974; Teetaert 1933) including a tract on evangelical poverty. Much of Pecham's work survives only in manuscripts, namely a considerable number of disputed questions and his commentary on the *Sentences* of Peter Lombard, the last three books of which appear to have been lost. A comprehensive assessment of his thought must await the critical edition of these works.

Peirce, Charles Sanders (1839-1914)

Peirce was an American philosopher, probably best known as the founder of pragmatism and for his influence upon later pragmatists such as William James andJohn Dewey. Personal and professional difficulties interfered with his attempts to publish a statement of his overall philosophical position, but, as the texts have become more accessible, it has become clear that he was a much more wide-ranging and important thinker than his popular reputation suggests.

He claimed that his pragmatism was the philosophical outlook of an experimentalist, of someone with experience of laboratory work. His account of science was vigorously anti-Cartesian: Descartes was criticized for requiring an unreal 'pretend' doubt, and for adopting an individualist approach to knowledge which was at odds with scientific practice. 'Inquiry' is a cooperative activity, whereby fallible investigators progress towards the truth, replacing real doubts by settled beliefs which may subsequently be revised. In 'The Fixation of Belief' *(1877), he compared different methods for carrying out inquiries, arguing that only the 'method of science' can be self-consciously adopted. This method makes the 'realist' assumption that there are real objects, existing independently of us, whose nature will be discovered if we investigate them for long enough and well enough.*

Peirce's 'pragmatist principle' was a rule for clarifying concepts and hypotheses that guide scientific investigations. In the spirit of laboratory practice, we can completely clarify the content of a hypothesis by listing the experiential consequences we would expect our actions to have if it were true: if an object is fragile, and we were to drop it, we would probably see it break. If this is correct, propositions of a priori metaphysics are meaningless. Peirce applied his principle to explain truth in terms of the eventual agreement of responsible inquirers: a proposition is true if it would be accepted eventually by anyone who inquired into it. His detailed investigations of inductive reasoning and statistical inference attempted to explain how this convergence of opinion was achieved.

Taken together with his important contributions to formal logic and the foundations of mathematics, this verificationism encouraged early readers to interpret Peirce's work as an anticipation of twentieth-century logical positivism. The interpretation is supported by the fact that he tried to ground his logic in a systematic account of meaning and reference. Much of his most original work concerned semiotic, the general theory of signs, which provided a novel framework for understanding of language, thought and all other kinds of representation. Peirce hoped to show that his views about science, truth and pragmatism were all consequences of his semiotic. Doubts about the positivistic reading emerge, however, when we note his insistence that pragmatism could be plausible only to someone who accepted a distinctive form of metaphysical realism. And his later attempts to defend his views of science and meaning bring to the surface views which would be unacceptable to an anti-metaphysical empiricist.

From the beginning, Peirce was a systematic philosopher whose work on logic was an attempt to correct and develop Kant's philosophical vision. When his views were set out in systematic order, positions came to the surface which, he held, were required by his work on logic. These include the theory of categories which had long provided the foundations for his work on signs: all elements of reality, thought and experience can be classified into simple monadic phenomena, dyadic relations and triadic relations. Peirce called these Firstness, Secondness and Thirdness. He also spoke of them as quality, reaction and mediation, and he insisted that the error of various forms of empiricism and nominalism was the denial that mediation (or Thirdness) was an irreducible element of our experience. Peirce's 'synechism' insisted on the importance for philosophy and science of hypotheses involving continuity, which he identified as 'ultimate mediation'. This emphasis upon continuities in thought and nature was supposed to ground his realism. Furthermore, his epistemological work came to focus increasingly upon the requirements for rational self-control, for our ability to control our inquiries in accordance with norms whose validity we can acknowledge. This required a theory of norms which would explain our attachment to the search for truth and fill out the details of that concept. After 1900, Peirce began to develop such an account, claiming that logic must be grounded in ethics and aesthetics.

Although pragmatism eliminated a priori speculation about the nature of reality, it need not rule out metaphysics that uses the scientific method. From the 1880s, Peirce looked for a system of scientific metaphysics that would fill important gaps in his defence of the method of science. This led to the development of an evolutionary cosmology,

an account of how the world of existent objects and scientific laws evolved out of a chaos of possibilities through an evolutionary process. His 'tychism' insisted that chance was an ineliminable component of reality, but he argued that the universe was becoming more governed by laws or habits through time. Rejecting both physicalism and dualism, he defended what he called a form of 'Objective Idealism': matter was said to be a form of 'effete mind'.

1 Life and works

Peirce's father, Benjamin Peirce, was one of the most respected American mathematicians of the nineteenth century. As well as holding chairs in mathematics and astronomy at Harvard, he was instrumental in establishing the American Academy of Arts and Sciences and served as Superintendent of the United States Coast Survey. Charles, whose remarkable intellectual abilities were soon recognized, was brought up in Cambridge, Massachusetts, in a house often visited by the leading philosophical and scientific figures of the time. Indulged and encouraged, his abilities were evident even in his most youthful writings. His undergraduate career at Harvard (1855-9) was undistinguished, but he was subsequently the first student to graduate *summa cum laude* in chemistry from the University's new Lawrence Scientific School.

By the late 1860s, Peirce's future looked bright. From 1861 he had worked as an aide to the Coast Survey. He lectured on logic at Harvard several times between 1865 and 1869. By 1867, his first important series of philosophical papers was appearing and he was elected to the American Academy of Arts and Sciences. In 1872 he founded a 'Metaphysical Club' where he discussed philosophical issues with kindred spirits, including William James, Chauncey Wright, Francis Abbot, and Oliver Wendell Holmes Jr. Although some friends already feared that Peirce's independence of mind and his difficult and wild personality would prove obstacles to academic success, his future seemed assured when, in 1879, he obtained a lectureship in logic in the new Graduate School at Johns Hopkins University. At Johns Hopkins, Peirce and a small group of talented students made important contributions to the logic of relations and the theory of probabilistic reasoning, and (independently of Frege) Peirce and his student O.H. Mitchell introduced quantifiers into logic (see Predicate calculus).

In the mid-1880s Peirce's professional life fell apart. His post at Johns Hopkins was suddenly terminated due to his personal irregularities, and his unreliability soon led to the end of his employment with the Coast Survey. Retreating to rural Pennsylvania, Peirce built a house where he lived with his second wife, often in desperate poverty, until his death in 1914. He was not wholly cut off from the academic world. His friendWilliam James arranged for him to give occasional series of lectures in Cambridge, Massachusetts - although he faced the widespread suspicion that he would be a bad moral influence upon the young students of Harvard. He continued to publish and he wrote many reviews for *The Nation*; and he produced eighty-thousand manuscript pages which are a major source for scholars trying to understand his later philosophical position. In 1903 he entered into an important correspondence with Victoria Lady Welby, an English scholar whose work in 'Significs' suggested a common interest with Peirce the semiotician. Lady Welby introduced Peirce's work to I.A. Richards and C.K. Ogden, whose account of them, *The Meaning of Meaning*, helped bring them to the attention of the wider philosophical community.

A finished statement of Peirce's philosophical system was never completed, but his published writings and manuscripts are extensive and range widely. During the late 1860s, a series of papers appeared, in the *Journal of Speculative Philosophy* and elsewhere, which summarized his early ideas on cognition, inference, logic, signs and the theory of categories. Attempts to incorporate this material into a textbook on logic in the early 1870s were thwarted, in part because of intractable problems about reference. However, material intended for this text surfaced, in a less systematic form, in Peirce's most famous series of papers, *Illustrations of the Logic of Science*, which appeared in the *Popular Science Monthly* in 1877-9. This included his best-known papers, 'The Fixation of Belief' and 'How to Make Our Ideas Clear', the standard source for his pragmatism. The most important work from the early 1880s was in formal logic, and *Studies in Logic*, a book of essays by Peirce and his students at Johns Hopkins, contained the Peircean version of the logic of quantification - which provided the key to solving his problems about reference.

The second half of the 1880s saw Peirce's interest turn to metaphysics and the revision of his theory of categories. An important series of five papers on metaphysical topics appeared in *The Monist* in 1891-3. Several attempts to collect his earlier papers in book form and to write a logic text survive from the following decade, including the

important *Grand Logic* of 1893. Constantly seeking funding to support various grandiose publishing ventures, Peirce made a very useful application to the Carnegie Foundation for support to write thirty-six ‘memoirs’ summing up his philosophical position in 1902. Although unsuccessful, the surviving drafts of the application cast invaluable light upon the structure of his thought. Also useful are lectures delivered at or around Harvard during this period. A fascinating series dealing with logical and metaphysical topics was given to the Cambridge Conferences in 1898 and has been published as *Reasoning and the Logic of Things*. After William James had made pragmatism famous, Peirce devoted much energy to displaying the superiority of his version of the doctrine, and he valuably seized the opportunity when invited to lecture on pragmatism at Harvard in 1903. He returned to the task of proving pragmatism in an incomplete series of papers published in *The Monist* a few years later. And it was around this time, in 1908, that he offered his ‘Neglected Argument for the Reality of God’: his view of God was somewhat pantheist, and he shared his father’s view of scientific research as an attempt to read God’s ‘great poem’, holding that scientific observation was a kind of religious experience.

2 Inquiry and the fixation of belief

In his writings from the 1860s and 1870s, Peirce explicitly questioned Cartesian assumptions about cognition. The papers in the *Journal of Speculative Philosophy* challenged the claim that we have introspective knowledge of our own mental states and disputed the foundationalist view that we have ‘intuitive’ knowledge - knowledge which is not logically dependent on prior opinions. The influence of the common-sense tradition emerges when Peirce criticizes Descartes’ use of the method of doubt. Cartesian doubt is impossible: it will be ‘mere self-deception and not real doubt’. Peirce enjoins us not to pretend to doubt in philosophy what we do not doubt in our hearts. Cartesians find the ultimate test of certainty in the individual consciousness, while Peirce urges us to follow the successful sciences in trusting to the critical conversation of a community of inquirers. And philosophy should follow the sciences in trusting the ‘multitude and variety of its arguments rather to the conclusiveness of any one’. Our experience of the growth of knowledge suggests that although we are fallible, we can make progress as members of a community of investigators. Descartes and his followers have provided no reason for us not to emulate this in philosophy. Peirce’s work on logic and epistemology attempted to vindicate this fallibilist but optimistic view of scientific inquiry. In the 1860s, he tried to do this by arguing that all thoughts are signs and all mental action is inference, and then explaining the grounds of our trust in the forms of reasoning that are used in science. We shall focus here on the arguments he employed in the following decade.

In ‘The Fixation of Belief’ (1877), Peirce is concerned with ‘guiding principles of reasoning’. These are propositions which formulate rules of inference: an inference is good if its guiding principle is true. Habits of reasoning express such guiding principles and almost any proposition could express one: to the proposition that all humans are mortal corresponds the rule that on hearing of the humanity of someone, their mortality may be inferred. However, Peirce is concerned with the special class of logical rules, of propositions that are ‘absolutely essential as guiding principles’ and he tells us that these are ‘necessarily taken for granted in asking whether a certain conclusion follows from certain premises’. The papers in the *Illustrations of the Logic of Science* attempt to draw out facts and principles which ‘are deduced from the assumptions which are involved in the logical question’, and which we must ‘already know before we can have any clear conception of reasoning at all’. He is hunting for the presuppositions of inquiry and with the fundamental norms which govern our participation in it.

The paper begins by characterizing inquiry which, we are told, starts with the posing of a question, with a real doubt, and concludes with the settled acceptance of an answer to the question, with belief. Both belief and doubt are characterized in a functionalist manner: beliefs are settled states which ‘guide our desires and shape our actions’; doubt is an unsettled state whose only effect on action is to provoke inquiry directed at its elimination. A genuine doubt is required to motivate inquiry (contrary to Cartesian doctrine) and once the doubt has been eliminated, inquiry comes to an end: ‘the sole object of inquiry is the settlement of opinion’. Since to believe something is always to believe it to be true, it is empty to say that our aim in inquiry is to arrive at the truth.

What methods should we use in order to settle opinions or fix beliefs? Peirce considers four: three prove unsatisfactory and the method of science is endorsed. It is the only method which is consistent with the presuppositions of inquiry, so the norms it provides are ‘absolutely essential’. Were we to adopt the method of tenacity, we would seize on any answer to our question, doing all that was required to ignore or resist anything that might persuade us to abandon it. The ‘social impulse’ prevents us from making this our method: our certainty will

inevitably be disturbed when we encounter people who hold other opinions and it is inevitable that we will do so. Proponents of the method of authority would allow a monarch or religious leader to choose an answer for an entire community and would control sources of available information to prevent our certainties being shaken. But this too will fail: no one could control opinions on *every* question, and we would eventually face problems through encountering people who are not subject to our chosen authority. The failure of these methods shows that we cannot live with a method which ignores the social dimension of inquiry or one that allows the correctness of an answer to be determined by the will of some individual. The a priori method meets these conditions: we are to accept the answer to our question which is ‘agreeable to reason’, the answer which seems most plausible. But this fails because the correctness of an answer remains a subjective matter: the method would be likely to make truth a matter of fashion.

The method of science introduces objectivity. It requires us to carry out inquiries in accordance with norms which reflect the following fundamental hypothesis:

> There are real things, whose characters are entirely independent of our opinions about them; those realities affect our sense according to regular laws, and, though our sensations are as different as our relations to the objects, yet, by taking advantage of the laws of perception, we can ascertain by reasoning how things really are; and any man, if he have sufficient experience and reason enough about it, will be led to the one true conclusion.
>
> (1992-4: 120)

Peirce’s arguments in favour of this method are rather unclear, but he strongly suggests that it alone is in harmony with ‘the logical question’. It is the only method ‘which presents any distinction of a right and wrong way’.

> The feeling which gives rise to any method of fixing belief is a dissatisfaction at two repugnant propositions. But here already is a vague concession that there is some *one* thing to which a proposition should conform. Nobody, therefore, can really doubt that there are realities…
>
> (1992-4: 120)

But Peirce also insists that everyone uses this method about ‘a great many things’, abandoning it only when unsure how to do so, and points to the triumphs of the scientific tradition as further recommendation. However the method of science has so far been formulated sketchily, and we should now examine Peirce’s attempts to fill in some of the details.

3 Pragmatism

Although Peirce did not use the word in print until more than twenty years later, ‘How to Make Our Ideas Clear’ (1878a) introduces the rule for achieving complete clarity about the contents of concepts, propositions and hypotheses which was later called ‘pragmatism’. The rule helps us to carry out scientific investigations in a responsible, self-controlled manner, but Peirce’s principle also has important applications within logic and philosophy. First, it is used to clarify concepts like reality and probability, which are fundamental to his understanding of the method of science. Second, its account of the meaning of propositions helps to explain how the method of science can indeed show anyone ‘the one true conclusion’ to an investigation. And third, it is needed to demonstrate that there are no important propositions - and none on which science depends - whose truth values cannot be established using the method of science. Peirce must show, for example, that all ‘ontological metaphysics’ is ‘gibberish’ (see Meaning and verification).

Peirce contrasts three grades of clarity in our apprehension of a concept or proposition. I possess the first when I unthinkingly apply the concept in my experience, and the second involves possession of an abstract definition. For example, we can define reality as ‘that which is not whatever we happen to think it’, but is unaffected by what we may think of it. These notions of clarity, familiar from rationalists’ talk of ‘clear and distinct ideas’, can appear sufficient only in the light of a discredited logic and philosophy. The third ‘pragmatist’ grade, Peirce later stressed, accords with experimentalist approaches to inquiry and laboratory experience. His formulation of his method for achieving this third grade of clarity is:

> Consider what effects, which might conceivably have practical bearing, we conceive the object of our conception to have. Then our conception of those effects is the whole of our conception of the object.

(1992-4: 132)

His examples, and his later formulations, clarify this obscure statement. For example:

> To say that a body is heavy simply means that, in the absence of opposing force, it will fall. This (neglecting certain specifications of how it will fall, etc., which exist in the mind of the physicist who uses the word) is evidently the whole conception of weight.

(1992-4: 133)

From the proposition that the body is heavy, I can derive conditional propositions predicting the experiential results of different actions: if I reduce the force acting to support the heavy body, it will fall. Pragmatism holds that I can provide a *complete* clarification of a concept by listing such conditional propositions: they tell me what effects my actions will have if the concept applies to a specified object. As Peirce insisted, this is an ‘experimentalist’s’ view of the content of propositions.

‘How to Make Our Ideas Clear’ uses the principle to clarify the concept of reality. Listing different methods for investigating the velocity of light, Peirce notes that, while users of each may initially produce different results, ‘as each perfects his method and his processes, the results will move steadily together towards a destined centre’. It is typical of scientific inquiry that ‘no modification of the point of view taken, no selection of other facts for study, no natural bent of mind even, can enable a man to escape the predestinate opinion’. Peirce’s clarification of the concept of reality is thus: ‘The opinion which is fated to be ultimately agreed to by all who investigate is what we mean by the truth, and the object represented in this opinion is the real’. Truth is defined by reference to long-run convergence of opinion among responsible inquirers: it is not independent of ‘thought in general’ but it is independent of what any individual may think at any particular time.

Another important application of Peirce’s principle is his account of probability, presented in the third paper of the series, ‘The Doctrine of Chances’ (1878b) (see Probability, interpretations of). Urging that we clarify the idea of probability by examining ‘what real and sensible difference there is between one degree of probability and another’, he follows Locke in identifying probability as a property of inferences. Deductively valid arguments are those which belong ‘to a genus of arguments all constructed in the same way, and such that, when their premises are real facts, their conclusions are so also. If the argument is demonstrative, then this is always so; if it is only probable, then it is for the most part so’ (1992-4: 146). The probability of a mode of argument is thus ‘the proportion of cases in which it carries truth with it’. A probability statement formulates a guiding principle for such an inference. If the probability of a tossed coin landing with heads uppermost is 0.48, then a claim is made about inferences from the premise that this coin was fairly tossed to the conclusion that it lands with heads uppermost: in the long run, such inferences will be successful around 48 per cent of the time. Pragmatism supports a frequency account of probability.

> As we go on drawing inference after inference of the given kind, during the first ten or hundred cases the ratio of successes may be expected to show considerable fluctuations; but when we come to the thousands and millions, these fluctuations become less and less; and if we continue for long enough, the ratio will approximate towards a fixed limit.

(1992-4: 146)

4 Induction and the method of science

So far, the method of science has been defined in terms of its underlying presupposition: for any question that we investigate, there is a correct answer which we are fated to reach if we carry out our investigations long enough and well enough. A more detailed account is needed of the scientific method and of how this convergence in opinion is to be secured. What inferences and methods should we employ, and how do they lead us to the truth?

Like other nineteenth-century thinkers, Peirce emphasized the self-correcting character of inductive reasoning: in the long run, error is sure to be eliminated and whatever survives testing will be the truth. Peirce’s development of this idea exploited an analysis of statistical sampling (‘quantitative induction’) which attempted to establish that successive sampling of a population is guaranteed eventually to discover the proportion of the population having a particular character. This was supplemented by the claim that all inductive inference can be modelled on statistical

sampling.

Suppose we wish to know the proportion of white beans in large bag of beans. Drawing out a handful, we find that 75 per cent of these beans are white. An inductive argument would then tentatively conclude that 75 per cent of the beans in the whole bag were white. So long as the handful is sufficiently large, and the beans in the bag are evenly distributed, the probability is high that the proportion of white beans in the bag as a whole is fairly close to 75 per cent. Moreover, if it is not, further sampling will arrive at a figure that is more accurate than the original one. The mathematical details of Peirce’s approach need not delay us, although we should note that this is in harmony with his pragmatist clarification of the concept of probability: if the probability of a bean drawn from the bag being white is 0.75, then as we draw more and more handfuls, we expect to find that 75 per cent of those that we draw are indeed white.

But quantitative induction forms only a small part of scientific inference. The experimental testing of theories involves an apparently different form of inference which is referred to as ‘hypothesis’ in Peirce’s earlier writings, and later as ‘qualitative induction’. But Peirce’s pragmatism reveals an analogy between quantitative and qualitative induction. For pragmatism holds that there is nothing to the content of a hypothesis apart from a set of conditional predictions, expectations about the experiential consequences we should expect our actions to have were the theory to be true. We are not in a position to test every one of those conditional predictions, although we can see that, if all were confirmed, the hypothesis would be true. When a hypothesis is tested empirically, then, we sample those predictions, and we infer from the success of the sample to the reliability of the ‘population’ of predictions forming the content of the hypothesis. The probability calculus is not applicable in these cases, of course, but as long as the pragmatist principle clarifies the full meaning of the hypothesis, the parallel cannot be denied.

There is an important difference between quantitative and qualitative induction. When subsequent sampling conflicts with my estimate that 75 per cent of the beans are white, it does so by introducing a revised estimate of the proportion: eventually, continued sampling will arrive at the correct figure. When evidence conflicts with a hypothesis in the course of qualitative induction, it does not introduce a replacement hypothesis. We depend upon our ability to think of promising hypotheses and to choose the right ones for empirical test. These matters are addressed in Peirce’s account of ‘abduction’. Much of the logic of abduction investigates methodological rules to be followed in deciding which hypotheses to test: we should prefer those that can be tested economically and whose falsity would be quickly exposed; we should also favour those that seem simple, cohere with our metaphysical views, or appeal to explanatory mechanisms similar to those that have been successful elsewhere in science. Many of these matters concern the economics of research: we plan our investigations in order to maximize progress and minimize expenditure of time, money and effort.

5 Abduction and critical common-sensism

More fundamental than this ‘economics of research’, however, is the ‘primary abduction’ on which all scientific activity depends, the presupposition or hope that we have a capacity for guessing right. We have a ‘natural instinct for the truth’: ‘the human mind is akin to the truth in the sense that in a finite number of guesses it will light upon the correct hypothesis’ (1931-58: 7, 139). Unless we can be confident that we shall think of a good hypothesis fairly soon, the motivation to carry out scientific research would weaken. Of course, this provides no reason for believing that the primary abduction offers, at best, grounds for hoping that it is correct. The history of science helps by showing that ‘it has seldom been necessary to try more than two or three hypotheses made by clear genius before the right one was found’.

Peirce’s account of the growth of scientific knowledge involves one further complexity. When first introduced, a hypothesis offers a vague picture which is incomplete and incorrect in many of its details: at best, we hope that some precise revision of it can be defended. Inductive testing will guide us in making revisions, in rejecting some adjustments and developing others:

> The familiar kinetical theory of gases illustrates this well. It began with a number of spheres almost infinitesimally small occasionally colliding. It was afterward so modified that the forces between the spheres, instead of merely separating them, were mainly attractive, that the molecules were not spheres, but systems, and that the part of space within which their motions are free is appreciably less than the entire volume of the

gas. There was no new hypothetical element in these modifications.

(1931-58: 7, 135-6)

This background to abduction will also contain beliefs and inferences drawn from common sense. Such beliefs and inferences are ‘acritical’: they cannot be subjected to critical evaluation and when asked to defend them we can say only ‘everything counts for them and nothing counts against them’. This slowly evolving body of opinions is indubitable and can almost be seen as instinctive. It is certain largely because common-sense beliefs are invariably vague: any proposed precise version of them would be fallible, but its defeat would not demonstrate that another way of making them precise cannot be found. General ideas drawn from analytical mechanics provide a common-sense framework against which research in physics develops, and the assumptions about beliefs, desires and meanings reflected in decision theory and microeconomics articulate the common-sense background to the social and human sciences. Peirce’s ‘critical common-sensism’ emphasizes the role of such instinctive certainties in grounding our policy of reflective critical inquiry. We should try to doubt such inferences and propositions in order to satisfy ourselves that they are indeed part of common sense, but, of course, we should not deceive ourselves into thinking that they are indeed dubitable on disreputable Cartesian grounds.

Although common-sense beliefs and vague theoretical pictures are hard to criticize, Peirce described himself as a ‘contrite fallibilist’: we are aware that most of our theories require revision and we anticipate that any of them might have to be abandoned (see Fallibilism). We look on them as currently accepted opinions, acknowledging that accepting them now is the best means to eventual progress towards the truth. In Peirce’s later writings, he expresses this fallibilism by denying that we should ever *believe* our current scientific results, and arguing that pure scientific research should be divorced from any concern with the useful applications which its results may have. Ironically, the method of science does not provide a means to the short-term fixation of belief.

Belief, according to Peirce, must result from instinct or sentiment, from the action of common sense, and he was scathing about those who trust theoretical reflection in connection with ‘vital’ matters. When facing important moral decisions or agonizing over the existence of God, we should spurn reflective deliberation, trusting instead our moral and religious sentiments, the instinctive manifestations of common-sense wisdom.

6 Architectonic and self-control

From around 1900, Peirce insisted that his work in logic and epistemology should be embedded in a systematic framework: a proof of pragmatism and a defence of induction were required, and his search for these led to the attempt to ground logic in aesthetics and ethics and to his development of phenomenology as a fundamental branch of philosophy. Why was he dissatisfied with his earlier defence of his views?

First (a minor point), he came to deny that we could establish that something is true by showing that it is a presupposition of inquiry: at best, that warrants our *hoping* that it is true. Hence his views risk refutation through a demonstration that what scientists hope to be true is not in fact so. Second, his pragmatism claimed that all scientific propositions can be fully elucidated using the pragmatic principle: there is nothing to their content apart from conditional predictions. Scientific work is shaped by explanatory ideals which guide us in establishing a *system* of knowledge. If concepts, such as continuity, which have a role in setting these ideals cannot be elucidated using the pragmatist principle, then Peirce’s pragmatism would be on shaky ground. He needed to show that such concepts were consistent with pragmatism - a conclusion his hero Kant would have denied. Moreover, he aspired to an argument for pragmatism which would convince even those who antecedently believed that they understood concepts that it would rule out of court. A particular threat concerned Peirce’s realism. He wished to take natural necessity seriously, and to claim that pragmatism was committed to the objectivity of ‘would-bes’ - to statements about what *would* occur in various possible situations (see §9 below). However, it is commonly assumed that the kind of verificationism that his position represents cannot make sense of the objectivity of ‘would-bes’. Many were convinced by Hume and others that verificationism required nominalism.

Finally, his argument for the superiority of the method of science claimed that the ‘social impulse’ acted against methods such as tenacity and authority. If this is a *psychological* claim about human inquirers, it is hard to see how it establishes the *normative* claim that only the method of science ought to be employed. Moreover, we have noted that since the method of science only promises to settle belief stably in the long run, requiring us to identify our interests with those of the wider community, we are required to use a different method (trusting to instinct) when

we try to settle vital questions. So, it seems, we do use an alternative method much of the time. Or if we use the method of science, confident that we can trust its results in connection with everyday matters, there is a question about the right with which we do so. And why is it rational for us to devote our lives to the cooperative pursuit of long-run stable settlement of beliefs? How can the search for the truth about reality be a good goal for us to adopt? It seems that Peirce must embed his views in a general theory of rationality, in a general theory of how we can order our lives in a self-controlled manner. Otherwise, his defence of the method of science begs too many questions.

By the late 1890s, Peirce was emphasizing that philosophy should have an architectonic character. It should be systematic and guided by a plan of the structure of knowledge as a whole. Thus he relied upon an explicit classification of the sciences, especially the philosophical sciences which can be schematized thus:

(1) Mathematics
(2) Phenomenology (or ‘Phaneroscopy’)
(3) Normative science:
(a) Aesthetics
(b) Ethics
(c) Logic:
(i) Speculative grammar
(ii) Critic
(iii) Methodeutic
(4) Metaphysics

Mathematics, our ‘practice of necessary reasoning’, needs no foundations, but provides techniques used by phenomenology to obtain a theory of categories from reflection upon all that appears to us in any way. Using these categories, the first two normative sciences provide an account of the rationality of ends: they identify what it is possible to admire unconditionally, and what it is possible to adopt as an unconditional end for conduct. Logic then investigates the norms governing inquiries: the first branch provides a systematic account of sign interpretation and reference; the second classifies arguments and explains their validity; and the third states and defends the methodological principles that guide inquiries. Peirce’s theory of truth is defended within his logic. Metaphysics develops a general scientific account of ‘the most general features of reality and real objects’. Together, these philosophical sciences explain the possibility of rational, self-controlled inquiry.

7 Categories, phenomenology and normative science

Throughout his career, Peirce’s philosophical ideas depended upon a system of categories, a set of universal conceptions which could be used to classify anything that could be experienced, thought about or imagined (see Categories). Growing out of his criticisms of Kant’s theory of categories during the 1860s, the system was subject to considerable development and refinement until the final decade of his life and had a fundamental role in grounding his other philosophical views. Although his terminology varied, he most commonly referred to these categories as ‘Firstness’, ‘Secondness’ and ‘Thirdness’. It is easiest to understand them by following Peirce himself in seeing how they are reflected in the logical forms of a ‘perfectly exact, systematic and analytic language in which all reasoning could be expressed and be reduced to formal rules’. Such a language might contain expressions like ‘… is red’ which express properties of a single subject as well as relational expressions such as the two place ‘…is taller than…’ and the three place ‘…gives…to…’. Peirce insisted that an adequate language would contain expressions of all these three kinds, and also that it need contain no expressions for relations between four or more objects. Concepts or phenomena are classified as forms of Firstness, Secondness and Thirdness according to whether they are expressed by general expressions which take one, two or three subjects. Firstness is what it is independently of anything else, Secondness involves what is in relation to something else, and Thirdness is manifested when something mediates between two others.

Peirce’s important 1867 paper ‘On a New List of Categories’ contained the first published version of the theory. It appeared before Peirce had worked much on the logic of relations and made no use of the terminology of Firstness, Secondness and Thirdness. However it was self-consciously Kantian in defending a system of categories by discussing what was required to reduce the manifold of sense to the unity of a proposition: Peirce spoke of

reducing the manifold of Substance to the unity of Being. We do so, he urged, by ascribing a quality to the substance, by classifying it or describing it. But how can we do that? Since 'we know a quality only by means of its contrast or similarity with another', we can ascribe qualities to things only because we can make relational judgments of similarity and difference. And we can make judgments of similarity only because we can carry out 'comparisons': we can interpret one object as a representation of another. So making sense of things by ascribing qualities to them depends upon our ability to make relational judgments and to work with the three-place relation of representation. All three categories are required for even the simplest kind of judgment. Peirce soon came to reject the assumption that quality (monadic characteristics) had a special role in unifying the manifold: the logic of relations led to the overthrow of Aristotelian logic and taught that relational judgments were just as fundamental as these simple monadic ones. Although this led to a reformulation of his theory of categories, he continued to use the argument of this early paper. He claimed that it embodied his 'one contribution to philosophy'.

With the development of the logic of relations, Peirce exploited his 'remarkable theorem' that it was impossible to define triadic relations in terms of simpler ones, whereas it was always possible to provide such definitions for relations with four or more relata. Within standard systems of the logic of relations, this does not hold: it is possible to reduce triadic relations to dyadic ones. However, recent scholarship suggests that Peirce's claim holds for his own systems of logic and that, for the purposes of constructing a system of categories, the Peircean systems are more perspicuous than those encountered in standard logic texts. Since this argument uses mathematics to defend the categories and mathematics was the foundational discipline without Peirce's architectonic structure, Peirce's continued reliance upon this argument is not surprising.

However, from the late 1880s new quasi-empirical arguments were introduced, culminating after 1900 in a phenomenological defence of them. 'A Guess at the Riddle' (1887-8) traced the 'triad' through logic and semiotics, in metaphysics, psychology, physiology and biology, and in physics and theology, thereby producing a 'long list' of categories. This investigation culminated in the development of Peirce's evolutionary metaphysics (see §10 below). Although not intended as a proof of the theory of categories, it was relevant to establishing a doctrine fundamental to Peirce's realism: Thirdness is found in the physical and biological realms as well as among mental and linguistic phenomena.

From 1903, Peirce undertook to defend his categories by looking 'directly upon the universal phenomenon, that is upon all that in any way appears, whether as fact or as fiction'. With the aid of special analytical techniques, his search again discovered the three fundamental categories, Firstness, Secondness and Thirdness. Since he remained convinced by the early 'logical' arguments, there is a question of why this further defence was required. The answer lies in Peirce's architectonic, his account of how the philosophical sciences all hang together. If the categories are to be used in logic and the other normative sciences, they must be defended in a more fundamental discipline. Since formal logic is a branch of mathematics, this may not seem problematic, but the logical argument for the categories required Peirce to show that a particular mathematical formalism could indeed be used as a system of formal logic: formal logic is, after all, a branch of *applied* mathematics. By showing that a formalism which incorporates the categories is adequate to describe 'all that in any way appears, whether as fact or as fiction', Peirce can be confident in relying upon his categories when he turns to the study of our attempts to discover the facts in logic.

Peirce's work in normative science seeks a theoretical account of what we can admire unconditionally (aesthetics), adopt as an ultimate end (ethics), or adopt as a fundamental goal for inquiry (logic). Thought experiments are employed: we consider different possible objects of experiments or imagine living with a particular aim in various counterfactual circumstances. In each case, the good consists in a manifold of phenomena each with their own qualitative character of Firstness, but standing in dyadic relations, reacting against each other. But this Secondness is mediated: the whole exhibits a coherence or unity which we can apprehend. Beauty, goodness and truth involve a kind of organic unity which excites our admiration, motivates our conduct and satisfies our inquiries. The method of science ensures progress towards a coherent body of opinions which brings our actions and experiences into harmony.

8 Signs and interpretations

Peirce's semiotic provides a wholly general theory of meaning and representation. An important move in his critique of the Cartesian conception of mind during the 1860s was that all thoughts and experiences are signs. In

later years, he used these semiotic conceptions to develop a sophisticated account of language - particularly of the language used by a 'scientific intelligence'. His philosophical account of science and mathematics focused upon the role of science interpretation in both, and important problems in the ontology of mathematics were answered by reference to the special character of the signs or representations used within that discipline. And the grounds of logic or deductive validity were traced to features of meaning and the sign relation. It is not surprising that Peirce described logic as 'only another name for *semiotic*, the quasi-necessary or formal doctrine of signs'. There are few of Peirce's writings that are not concerned with questions of meaning and signification.

His work exploits the fundamental insight that signification is a form of Thirdness. The sign relation is irreducibly triadic, and the third element in this relation is interpretation. A name denotes an object or a sentence stands for a state of affairs by virtue of being interpreted in subsequent thought, speech or action as doing so. The interpretant, which is itself a sign with the same object, thus mediates between the original sign and its object. Thus my understanding of a report that an animal before me is a cat can be variously manifested in my explicitly thinking or saying that this is what the utterance means, in my inferring that the animal probably likes milk, in my offering it cat food, or in my showing surprise when in suddenly barks. Unless the sign has the capacity to produce such interpretant thoughts (the meaning of which in turn depends upon how they are interpreted) it would have no significance. Since a thought too is a sign, the content of a thought (or any other mental event) is determined by how it is interpreted and developed in subsequent thought. In general, the content of a thought or utterance depends upon its effects.

Much of Peirce's writings about signs was directed at constructing a classification of types of signs: he sought an exhaustive classification of signs, objects and interpretants. One motivation for this was Peirce's desire to defend the pragmatist principle by showing that it would enable us to be reflectively aware of all those features of how a sign should be interpreted that were relevant to our scientific purposes. He argued that the 'ultimate logical interpretant' of a sign was a habit of expectation which could be fully described by application of the pragmatist principle. Some of the classifications are of more general interest, offering important insights into thought, language and other forms of representation. And his writings on signs contain valuable contributions to the understanding of mental phenomena such as emotions, sensory experiences and religious experience as well as interesting discussions of proper names, vagueness, conditionals, modality, quantification, force and content and other live issues in the philosophy of language.

The question of how we are guided in arriving at interpretations of signs introduces the best known of Peirce's classifications, that between icon, index and symbol. Roughly, interpretation of an iconic sign is grounded in a resemblance between the sign and its object, interpretation of an index exploits a 'real existential relation' between the two, and we can defend our interpretation of a symbol by reference to an established practice of so interpreting it. Photographs and maps are icons, signposts and pointing fingers are indices, and it is easy to see that natural language has a strong symbolic component. The utterance of a symbolic sign is always a *replica* of the symbol (a token of the type), and its interpretation appeals to the interpretations offered of other replicas or tokens. Peirce denied that there were 'pure' icons or indices. Maps and signposts are 'hypo-icons' and 'hypo-indices', having a strong conventional component. The rules governing the use of maps do not fix the interpretation of particular features of the map unaided: they rather guide us in how to use it as an icon. Similarly, although we are able to understand pointing fingers only because we are masters of the practice of doing so, the rules of this practice do not explicitly lay down what a particular finger is pointing at. Rather, they guide us in how to interpret the finger as a conventional index.

This classification exploits Peirce's system of categories. Interpretation of an index depends upon a dyadic existential relation between sign and object: it exploits properties the sign would lack if its object did not exist. When we understand a symbol, we appeal to triadic features of the sign, such as how its replicas have been interpreted in the past. And an understanding of icons exploits common features of sign and object which each could have, even if the other had not existed. In his 1885 paper, 'On the Algebra of Logic: a Contribution to the Philosophy of Notation', Peirce announced that an adequate language for descriptive or scientific purposes must contain signs of all three kinds. Indeed, any proposition must have symbolic, iconic and indexical components. Indices such as names, demonstrative expressions, pronouns and quantifier expressions are required if the proposition is to speak of any external things at all: the universe of discourse must be specified indexically. Symbols are the only general signs, and generality is essential to reasoning: we must be able to recognize that

premises and conclusions contain tokens of the same word or phrase type, replicas of the same symbol.

The value of iconic signs is that we can exploit their similarity with their objects, learning more about the latter by noting features of the icon. We can make discoveries about the terrain by making measurements on a map, or learn more about a building by examining a photograph. A proposition provides a sort of diagram of a state of affairs, mirroring its logical structure. Inference exploits this abstract resemblance: we learn more about the world by making substitutions in propositions in the light of other information that is to hand and observing the result of our ‘experiment’. This is clearest when we think of formal logic, which, like all of mathematics, constructs iconic representations of the structure of propositions and arguments which enable us to investigate the validity of arguments. Unless descriptive propositions were icons and shared abstract structural properties with their objects, Peirce argued, we could make no sense of how reasoning can provide us with new knowledge. The formal character of reasoning shows that we interpret propositions as icons. So any language is a device for constructing conventional, logical diagrams which are tied down to concrete, existing things through the use of indices.

After 1900, Peirce sought a proof for his pragmatism. He needed to show that no aspect of the meaning of a proposition, nothing relevant to its cognitive functioning, was omitted when we clarify it using the pragmatist principle. One strategy was to develop his theory of signs and show that interpreting a proposition in the light of pragmatism produced its most explicit (‘ultimate’) logical interpretant. Another strategy was to construct a complete classification of argument forms and to show that we needed no information missed by a pragmatist elucidation in order to employ a proposition in reflective, controlled argument. An important tool here was the system of existential graphs (see Logic machines and diagrams). A system of formal logic analogous to later natural deduction systems, the graphs promised ‘moving pictures of thought’ which would exhibit the structure of all possible forms of argument. As well as a complete system of propositional and predicate calculus, the graphs promised an account of sophisticated reasonings involving modality, continuity and abstraction. If all reasoning is reflected in the system of existential graphs, and if the pragmatic principle is true for all concepts whose conceptual role is modelled within them, then the pragmatist is vindicated. Unfortunately there is little evidence that Peirce completed the graphs to his satisfaction.

9 Realism

Peirce described himself as a realist, rejecting nominalism and epistemic idealism as the source of most philosophical ills (see Nominalism; Realism and antirealism). This can be surprising because pragmatism is often understood as an antirealist, verificationist doctrine.
